Then followed a long pause between fish and soup, during which the talk of the guests and the tones of the band rendered it very difficult to do more than catch a few words from the nearest neighbours. Then, just as some of the visitors had swallowed a few mouthfuls of fish, silence was again called, the Rector rose, the waiters stopped, the guests stood up wiping their mouths, and the health of Kaiser Wilhelm was given and received with all honours, while the band played the familiar air of "God save the King."

Toast after toast followed, and pause after pause ensued, until seven o'clock was reached, when the guests departed, many to see their friends, many to the theatres.

In the evening there was a great gathering of the students and their friends, and of all who had come to the festival, in the great Ludwigshalle. If the official performances were singularly silent, this cannot be said of the "Bankett der Studentschaft," the hilarious mirth of which was audible far beyond the limits of the hall. But good humour prevailed throughout, and the festivities were not prolonged until an unduly late hour.

This leads me to make a remark, and the only one that is tinged with sorrow, about this festival, and that is with regard to the painful spectacle of the gashed and disfigured cheeks, brows, and noses of dozens of students who were going about Würzburg and Heidelberg. Many had scars, of three to five inches long, on either cheek, some had slit noses, and were adorned with plaster as their only "decoration"; while some grown-up men were to be seen, who must have left their colleges for ten or fifteen years, still bearing these ghastly signs of early folly.

The man who has received his wounds in honest fight for his country or his home may be proud of what he has done, but he is not vain of his wounds. But these young men, of seventeen to twenty years of age, stamp about the street, or, curiously enough, ride in carriages behind a pair of horses, with their disfigured, and often injured heads, tossed high in the air as if they thought it a fine thing to make day as well as "night hideous" in remembrance of something which has not been an honourable quarrel, but a form of strife for which few can entertain any feeling of respect.

The University of Würzburg may reasonably take pride in its catholicity; but the University of London has far surpassed it in the practical results of its thorough freedom from all tests of membership, instruction, or honours, for in my class alone in University College there have been Jews, Turks, Hindoos, Japanese, West Indians, and men of every persuasion of Christian faith. But the University of Würzburg is doing a grand work, and with it, in its endeavour, and successful endeavour, to making teaching as efficient as it can be made, and as wide in its range of influence to "all sorts and conditions of men," we hail it with all honour as an elder worker in the broad field of general education.

Nothing could exceed the careful thought with which every arrangement for the assistance of delegates and visitors was made, unless, indeed, it be the kindness and hearty hospitality with which such visitors were greeted.

MR. J. J. MILNES, a Huddersfield solicitor, has obtained a verdict against the Corporation of that town, at the Leeds Assize, for £2000, as compensation for personal injuries caused by drinking impure water supplied by the Corporation. The water in its passage through the service pipes had become so impregnated as to produce in the plaintiff's case every symptom of acute lead-poisoning. A point as to the liability of the Corporation was reserved.

### PROSECUTION UNDER THE BIRTHS AND DEATHS REGISTRATION ACT, 1874.

At the Clerkenwell Police-court, on Wednesday, the 2nd inst., before Mr. Barstow, John Henry Friend, of Dean's-court, Goswell-road, was summoned by the Medical Defence Association for having forged a certificate or declaration for the purposes of the Births and Deaths Registration Act, 1874, concerning the body of the deceased child of Alma Smith. A second summons charged him with having made, given, and used a false statement or representation concerning the body of the deceased child; and a third with having unlawfully procured the burial of the said child under the representation that it was still-born.

Mr. Pridham, Solicitor to the Association, conducted the prosecution.

The prisoner pleaded guilty to the first two summonses, and not guilty to the third. The third summons was afterwards withdrawn.

Mr. Pridham said the deceased was the illegitimate offspring of Alma Smith, the defendant being the father. No medical man was called in to attend the mother, but she was attended in her confinement by the defendant's mother, who stated that the child was still-born, and called in an undertaker, named Bright, to bury it. The undertaker stated that he could not do so without a certificate, and two days after the child's death, Bright was sent for by the defendant, who handed him a document, of which the following is a copy:—

"July 3rd, 1882.

Dr. Clift, 81, Central Street, St. Luke's.

I hereby certify that I delivered Mrs. Smith of a female child (still-born) on the 1st of July, at No. 4, Thomas-place, Goswell-road.

Given under my hand,

Dr. CLIFT,

81, Central Street, St. Luke's."

The original certificate was shown to Mr. Barstow, who, remarking on its illiterate appearance, stated that the undertaker must have known this was not a proper certificate, and Mr. Pridham concurred in his opinion. Mr. Pridham, continuing, said the child was buried at Manor Park Cemetery, Forest-gate; but the superintendent of the cemetery noticed the informal character of the certificate, and forwarded it to the district registrar, who sent it to the coroner for Central Middlesex, and the result was that the body was exhumed and an inquest held. Dr. Clift never saw or attended Alma Smith or gave a certificate, and the document produced was, as the defendant now admitted, a forgery.

Mr. Barstow remarked that this was a very serious offence, and one for which a few years ago the prisoner might have been hanged. He inflicted a penalty of £5 and costs on each summons, or two months' imprisonment.

Defendant was unable to pay the fines and costs, and was therefore removed to the cells to undergo the imprisonment.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Brighton (Urban).*—Dr. Taaffe's annual report on the health and sanitary condition of this popular watering-place and health-resort, during 1881, acquires additional interest from the unfavourable mortality statistics recorded there during the first half of this year, which attracted so much public attention. The estimated population of Brighton in the middle of last year, based upon the results of the Census in April, was 107,934, and the town is one of the twenty-eight largest English towns embraced by the Registrar-General's Weekly Return. The constitution of the population of this large watering-place is exceptional, as may be inferred from the fact that both the birth-rate and the death-rate in Brighton are almost invariably lower than those recorded in any of the other large towns in the Registrar-General's Weekly Return list. During last year the birth-rate in the borough was but 30·6, and the death-rate 19·0

per 1000; these rates were respectively 5·0 and 2·7 below the mean corresponding rates in the aggregate of the twenty large towns. It would be interesting to know how much the mortality statistics is affected by the exceptional age-constitution of the population, but Dr. Taaffe does not give the means for estimating this disturbing element. The normal birth-rate is usually higher in populations having low death-rates than in those having high death-rates. On the other hand, death-rates are almost invariably low in the suburbs of all large towns, where domestic servants form so large a proportion of the population, and yet scarcely contribute to the local rate of mortality. It is certain that on these accounts it would be most misleading to base any conclusions as to the sanitary condition of Brighton on the comparison of its gross death-rate with that of the other large English towns dealt with in the weekly return, consisting, as they mainly do, of London, and manufacturing towns of the midland and northern counties. At the same time it must be admitted that in the death-rate competition with other watering-places and health-resorts, Brighton is heavily handicapped with its population of over a hundred thousand, the bulk of which is thoroughly urban in character and density. Dr. Taaffe's report shows that in St. Peter's sub-district, with its central population of over 60,000, the birth-rate last year was 35·9 and the death-rate 22·3; whereas in the other sub-districts, including the outer ring of Brighton, with a population of about 45,000, the birth-rate was only 23, and the death-rate less than 15 per 1000, sufficient proof of the abnormal constitution of the population. There is another fact which should not be lost sight of when basing conclusions upon the gross death-rate of most watering-places, which is that visitors, while almost constantly forming a large proportion of the population, contribute very slightly to the rate of mortality. Dr. Taaffe notes that only 159 of the 2039 deaths during last year were of non-residents, but he does not state his definition of a non-resident. The zymotic death-rate is always, and especially so in the case of health resorts, one of the most important tests of the temporary sanitary condition of such towns. No one would be wise to select as a health-resort one in which the death-rate from zymotic disease was at the time excessive. The deaths referred to the principal zymotic diseases in Brighton last year were 241, equal to a rate of 2·2 per 1000 of the population, and 11·7 per cent. of the deaths from all causes. These zymotic deaths included 73 from scarlet fever, 52 from diarrhoea (mainly infantile), 45 from "fever" (mainly enteric), 22 from whooping-cough, 23 from measles, 9 from small-pox, and 7 from diphtheria. The zymotic death-rate as well as the gross death-rate showed a considerable excess in St. Peter's sub-district. Scarlet fever was more fatal in Brighton in 1880 and 1881 than in any year since 1871. The new sanatorium, if turned to good account, should be the means of reducing the mortality from scarlet fever. The deaths from enteric fever were more numerous last year than in any of the eleven preceding years. The outbreak last autumn is attributed by Dr. Taaffe to milk dissemination. It is reported that 25 per cent. of the deaths from all causes resulted from diseases of the respiratory organs and phthisis; the death-rate from these causes, however, was lower than in any recent preceding year. Infant mortality was also satisfactorily low. From a statistical point of view, the value of Dr. Taaffe's report would be much enhanced by a summary table, for comparative purposes, showing uniform figures for a series of years. The quotation of strings of figures in the report itself undeniably encumbers the text; the necessity for this would be obviated by the addition of a comparative table. The statistics of the past twelve years show a considerable decline in the death-rate, which averaged 21·5 per 1000 in the first, and fell to 19·6 per 1000 in the second half of this period. This at any rate is a satisfactory feature in the recent sanitary statistics of the borough. The Brighton death-rate in recent years has undoubtedly compared favourably with those of the Registrar-General's other large towns; but before this can be too implicitly relied upon in proof of satisfactory sanitary condition, it would be well to ascertain what the death-rate ought to be. At the same time, as a watering-place, the reputation of the town must invariably suffer, at any rate, temporarily, whenever excessive zymotic fatality prevails. In the interest of public health it is most desirable that this should be the case, and it is therefore of the first importance to the welfare of a watering-place that no effort should be spared to secure the early report of all cases of infectious disease, as well as the hospital isolation of all

cases in which efficient house isolation is impossible. Dr. Taaffe reports that 454 inhabited houses, &c., were connected with the main drainage during last year, but that nearly 6000 connexions still remain to be made.

*Ware Rural Sanitary District.*—In his report on this district Mr. Turner refers to several matters of interest. He points out the inefficiency of the disinfecting stove in use in the district, a stove, which he alleges, cannot properly disinfect except at the risk of burning. We fear there are many hot-air stoves in use, in various sanitary districts, as to which the same may be said. They are often so constructed and so heated that uniformity of temperature in all parts of the stove is impossible, whereas this condition is one which should always be insisted on. It is a matter of common experience to find stoves registering a temperature of some 150° to 200° F. only, whilst articles within, and which cannot burn under some 270° to 280° F., are being destroyed. Such stoves should invariably be avoided, and none should be procured in which a fairly uniform temperature of about 250° F. cannot be ensured in all parts of the stove, and in the interior of such articles as pillows. Mr. Turner next expresses an opinion strongly condemnatory of country fairs as facilitating the spread of infectious diseases. These fairs are now rarely occasions where any real business is done, many have been abolished, and those that remain serve little or no useful purpose. Speaking next as to the serious need for a proper water-supply for the hamlet of Hoddesden, and for Broxbourne and other places, Mr. Turner refers to the working of the Public Health Water Act. He reminds the sanitary authority that the provisions of this Act can only be brought into operation provided each house can be supplied at a cost not exceeding £8 13s. 4d.; but as this is rarely possible in a country district, the cost of making the provision has to fall, not on the owner of the property having no water, but on the whole body of ratepayers. Many complaints have been made as to this, an arrangement which, as Mr. Turner observes, offers an inducement to unscrupulous owners of property to delay making a proper provision, as regards water, until the neglect becomes a local scandal, and then the burden is thrown upon all parishioners alike.

*Ventnor (Urban).*—Dr. Woodford, the medical officer of health for the urban sanitary district of Ventnor, has recently issued his report on its health and sanitary condition during last year. The mortality statistics of the year indicate that the health of the town last year was eminently satisfactory. Not only was the general death-rate low, but the rates of zymotic fatality and infant mortality were considerably below the average. The population of this sanitary district increased from 4841 in 1871 to 5684 at the census last year. The unusually low birth-rate of 20·7 was recorded, showing that the constitution of the population as regards age and civil condition must be very different from that which prevails in most urban districts. The 104 deaths during the year were equal to a rate of 18·3 per 1000 of the estimated population. Dr. Woodford naturally, however, points out that this death-rate cannot be accepted as fairly representing the rate of mortality of the resident population, as 16 of the 104 deaths were recorded in St. Catherine's Home for advanced consumption, and 33 of the other deaths are stated to have been not of inhabitants, "but of strangers who are known to have come into the district with their fatal illnesses upon them." Making this deduction, Dr. Woodford arrives at the conclusion that 9·6 per 1000 was the more correct death-rate in Ventnor during 1881. There can be no question that the deaths of consumptive visitors recorded in Ventnor, whether in hospital or in private houses, may fairly be excluded from the estimation of the true death-rate of the residents of Ventnor. It would, however, be desirable to know what is Dr. Woodford's precise definition of a resident and of a stranger. The population of Ventnor is too small to yield mortality statistics for a single year which may safely be used for comparative purposes, but the corrected death-rate of 9·6 strongly suggests over-correction, although this exceptional rate may be due to the frequent wide variation of results calculated from small numbers. In point of fact Dr. Woodford makes the corrected death-rate of the preceding year 18·2 per 1000. There can be no mistake, however, about the satisfactory conclusions to be drawn from the comparative freedom from fatal zymotic disease enjoyed by Ventnor last year. Two deaths, each from typhoid fever, and two from puerperal fever, were the only fatal cases of the principal zymotic diseases; no death being referred either to measles,

scarlet fever, small-pox, diphtheria, or whooping-cough. Notwithstanding this favourable bill of health it is unsatisfactory to hear that "no success has attended the board's efforts to establish a hospital for infectious diseases." The public has a right to expect health resorts to provide themselves with such hospital accommodation in the interest of their visitors. It is undoubtedly a step in the right direction, that the sanitary authority is prepared to give sanitary certificates to houses which fully comply with the requirements of the authority. Only sixteen of such certificates have yet been granted in Ventnor, and it really rests with public opinion to bring pressure to bear upon lodging-house keepers, in order that they may learn to recognise the desirability of obtaining these certificates.

*Belfast.*—For the four weeks ending July 22nd, the births registered amounted to 494, and the deaths to 336, including 47 deaths from zymotic diseases and 117 from diseases of the respiratory organs. One death from small-pox was recorded during the month. The death-rate was equal to 21 per 1000. There has been a considerable decrease in the number of cases of small-pox and also of typhus fever; and the only zymotic disease that has exhibited an increase is diarrhoea, probably due to the unripe fruit used causing gastric and intestinal affections.

*Cork.*—During the four weeks ending July 15th 143 births occurred, being equal to 23·07, and the deaths to 124, or 20·50 per 1000. Deducting the deaths occurring in the workhouse the urban death-rate was 15·09. Fever of every description, especially typhus, has shown a decided decrease as compared with the previous return.

#### ASHPIT NUISANCES.

The *Local Government Chronicle* records some proceedings which were taken at Chesterfield in order to secure the abatement of a nuisance arising from certain uncovered ashpits. These receptacles were alleged by the medical officer of health and the inspector of nuisances for the borough to contain liquid contents, which soaked through the walls and, hence, to cause an offensive nuisance. A physician, who was apparently one of the defendants, to our astonishment, undertook to defend these structures before the bench, declaring that ashpits ought to be uncovered and that the proposal to cover them in was in disregard of the true laws of health and sanitation. In one sense, perhaps, the defendant was right. If ashpits and similar receptacles for vegetable and other filth are to be left exposed to rainfall and soakage—an arrangement which will certainly facilitate the rapid decomposition of their contents,—it may be doubtful how far it is wise to hide the sloppy stuff under a cover, rather than let it be open to view, for where so exposed the tenant more immediately concerned will get such advantage as may result from the emanations being blown from his own into his neighbours' premises, and the district as a whole will at least be able to see to what the nuisance is really due. But here all advantage ceases. Ashpits should be so constructed, both by being raised somewhat above the surrounding ground and by being covered in, as to prevent that wetness of contents which is due either to soakage into them of subsoil water or to rainfall. Since it is precisely this wetness which does the harm, the need for a place open to such breezes as will carry away foul effluvia will then be practically gone. In short, it is dryness of contents which must, as far as possible, be secured; for the drier the refuse, the less chance is there of that decomposition which leads to nuisance and injury to health. The Chesterfield magistrates acted wisely; they accepted as correct the opinion of their medical officer of health, and ordered that the nuisance resulting from the uncovered ashpit should be abated.

#### VITAL STATISTICS.

##### HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns, 5748 births and 3270 deaths were registered during the week ending the 5th inst. The annual death-rate in these towns, which had been equal to 19·0 and 19·6 in the two preceding weeks, further rose last week to 20·1. The lowest rates in these towns last week were 10·6 in Derby, 13·3 in Halifax, 13·8 in Brighton, and 14·9 in Bristol. The rates in the other towns ranged upwards to 25·0 both in Sunderland and Huddersfield, 25·1 in Liverpool, 26·9 in Leicester, and 30·8 in Man-

chester. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 699, showing a further increase of 64 upon recent weekly numbers; 390 resulted from diarrhoea, 86 from scarlet fever, 78 from whooping-cough, 74 from measles, 50 from "fever" (principally enteric), 16 from diphtheria, and 5 from small-pox. The lowest death-rates from these diseases last week occurred in Plymouth and Oldham, and the highest in Hull, Sunderland, and Leicester. Whooping-cough caused the highest death-rates in Birkenhead and Preston; scarlet fever in Derby and Sunderland; measles in Hull and Sunderland; and "fever" in Derby and Hull. The fatal cases of diarrhoea in the twenty-eight towns last week showed a further marked increase upon recent weekly numbers, but were again considerably below the average for the season; the highest death-rates from this disease were recorded in Sunderland and Leicester. Of the 16 deaths from diphtheria in the twenty-eight towns 15 occurred in London, and 1 in Hull. One fatal case of small-pox was recorded in London, 3 in Newcastle-upon-Tyne, and 1 in Hull. The number of small-pox patients in the metropolitan asylum hospitals, which in the fourteen preceding weeks had declined from 350 to 159, further fell to 133 on Saturday last; 16 new cases of small-pox were admitted to these hospitals during last week, against 20 and 10 in the two previous weeks. The deaths referred to diseases of the respiratory organs in London, which had been 157 and 183 in the two preceding weeks, further rose to 193 last week, and were 22 above the corrected average number in the corresponding week of the last ten years. The causes of 75, or 2·3 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Norwich, Nottingham, Derby, and Bolton; whereas the proportions of uncertified deaths were largest in Sunderland, Wolverhampton, Salford, and Preston.

#### HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had been equal to 21·7 and 21·3 per 1000 in the two preceding weeks, was again 21·3 in the week ending 5th inst.; this rate exceeded by 1·2 the mean rate last week in the twenty-eight large English towns. The deaths referred to the principal zymotic diseases in these Scotch towns were 112 last week, and differed but slightly from the number in the two previous weeks; they included 55 from diarrhoea, 17 from measles, 13 from whooping-cough, 10 from "fever," 10 from diphtheria, 7 from scarlet fever, and not one from small-pox. The death-rate from these principal zymotic diseases averaged 4·8 per 1000, and was 0·5 above the mean rate from the same diseases in the large English towns. The 55 deaths attributed to diarrhoea in the eight towns showed a decline of 9 from the number in the previous week, but exceeded by 7 the number in the corresponding week of last year. The fatality of diarrhoea in the Scotch towns continues to show a marked excess upon that recorded in the English towns; the largest proportional excess occurred in Glasgow and Greenock. The 17 fatal cases of measles showed an increase of 10 upon the number in the previous week, and included 7 in Dundee and 6 in Leith; 38 fatal cases of measles have occurred in Dundee since the beginning of July. No fewer than 10 of the 13 deaths from whooping-cough were returned in Glasgow. The 10 deaths referred to "fever" included 3 in Glasgow, 3 in Edinburgh, and 2 in Dundee; while the 10 fatal cases of diphtheria, of which 5 occurred in Glasgow and 2 each in Aberdeen and Greenock, showed an increase upon recent weekly numbers. The 7 deaths from scarlet fever included 3 both in Glasgow and Paisley. The deaths referred to acute diseases of the lungs in the eight towns, which had been 95, 80, and 82 in the three previous weeks, declined to 74 last week, and were fewer by one than those attributed to these diseases in the corresponding week of last year.

#### HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 21·9 and 20·8 per 1000 in the two preceding weeks, rose again to 22·9 in the week ending the 5th inst. During the first five weeks of the current quarter the death-rate in the city has averaged 20·6 per 1000, against 18·1 in London and 18·6 in Edinburgh. The 153 deaths in Dublin last week showed an increase of 14 upon the low number returned in the pre-

vious week, and included 7 which were referred to "fever" (typhus and enteric), 6 to diarrhoea, 2 to measles, 1 to diphtheria, and not one either to small-pox, scarlet fever, or whooping-cough. Thus 16 deaths resulted from these principal zymotic diseases, against 8 and 12 in the two preceding weeks; these 16 deaths last week were equal to an annual rate of 2·3 per 1000, against 3·7 in London and 2·9 in Edinburgh. The deaths referred to different forms of "fever," which had been 3 in the previous week, rose last week to 7, and exceeded the number returned in any week since April last. The fatal cases of diarrhoea were 6 last week, against 7 and 5 in the two preceding weeks. The 2 deaths attributed to measles were one less than the number in the previous week. The fatal case of diphtheria was the first recorded in the city since the commencement of the current quarter. The deaths of infants showed a slight further increase upon recent weekly numbers, while those of elderly persons were less numerous. The causes of 20, or 13 per cent., of the deaths in the week were uncertified.

#### THE SERVICES.

ARMY MEDICAL DEPARTMENT.—Surgeon-Major Richard Turner, M.D., has retired upon temporary half-pay. Surgeon John Mulrenan, M.D., has retired upon temporary half-pay.

RIFLE VOLUNTEERS.—19th Lancashire (not Lanarkshire, as misprinted last week): James Booth Clarkson, Gent., to be Lieutenant.

ADMIRALTY.—The following appointments have been made:—Staff Surgeon James H. Martin (additional), for medical charge of crews of the transports in Egypt; Staff Surgeon Edward Meade to be Fleet Surgeon; Surgeon John O'Callaghan, B.A. (additional), for charge of crews of the transports in Egypt; Surgeon William Brown and Surgeon John Cassilis Birkmyre Maclean, M.A., M.B., to be Staff Surgeons, the latter reappointed on promotion to the *Alexandra*; Fleet Surgeon William Henry Cruice, to the *President* (additional); Staff Surgeon William Browne, to the *Monarch* (reappointed on promotion); Surgeon John William Davis, to the *Duncan*, vice William F. Spencer.

In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet Surgeon Bradley Gregory has been placed on the Retired List of his rank.

Dr. George Chadwick has been appointed Surgeon and Agent at Lynn and detachments, vice Mr. Woodward.

#### Correspondence.

"Audi alteram partem."

#### EDUCATION IN SCOTLAND.

To the Editor of THE LANCET.

SIR,—Permit me to rectify a slip made by your esteemed correspondent last week, in saying of a recent address by me that I "showed that while in regard to the Arts course the Scottish Universities were perhaps behind those of England and Germany, such could not be said of the medical." I should be sorry, indeed, to make any such statement in regard to our Arts education. What I said of the Arts course was: "The Arts students in Scotland are, on an average, younger than in England and Germany, and that this might be, to some extent, changed with advantage, and also some reasonable amount of option allowed in the studies for the Arts degree, is now pretty well agreed, and it is for such objects mainly that the appointment of a Universities' Commission is expected soon. But as to the Arts studies in the two kingdoms, it is a question which system is the better one. The Scottish system is one intended for the education of the professions, and for those of the commercial world whose parents appreciate the value of a good education. The youth is sent to a Scotch University to work, which also means economy; while to Oxford or Cambridge he goes with a large sum of money in his pocket. This may suit a certain section of the community in England, but that the Scottish system is the better of the two for the life and progress of the nation few will doubt, and it may be said that what England wants for its higher education is a number of universities, in its chief centres, modeled on the Scottish system."

Since the publication of the Report, of 1880, of the Committee of the House of Commons on the Medical Acts Amendment Bill, we have heard little of that criticism of the medical system of the Scottish Universities with which we had been before favoured from London, and we shall have still less of it now that the Report of the Royal Commission on the Medical Acts is published. We are now being lectured from England on our Arts system in the style in which lofty people write of that which they do not understand. The more our English friends look into the system of the Scottish Universities, the more they will perceive that it is a system which English reformers would do better to try to copy than to criticise.

I am, Sir, yours truly,  
 Aberdeen University, August 7th, 1882. JOHN STRUTHERS.

## SURGICAL DRESSINGS.

*To the Editor of THE LANCET.*

SIR,—Dr. Edward Thompson in your issue of the 29th ult. recommends the use of the dry puffball (*Lycoperdon giganteum*) as a hæmostatic and surgical dressing. The part used is the interior, consisting of the dry capillitium and spores. I have seen many cases in which this substance has been used as an hæmostatic, for there is hardly a farmhouse in this district in which a dry puffball is not to be found stored up against an emergency. The great disadvantage in its use is that, although undoubtedly a powerful hæmostatic, so tender is the substance, and so firmly does it cling to the interior of a wound, that it is almost impossible to completely remove it, and I have had many a tedious half-hour when I was house-surgeon attempting to do so. While undoubtedly a powerful agent in arresting non-arterial hæmorrhage, its use is at the same time inimical to union by first intention.

I am, Sir, yours truly,  
 King's Lynn, August 3rd, 1882. CHARLES B. FLOWRIGHT.

## THE COSTLINESS OF MEDICAL BOOKS.

*To the Editor of THE LANCET.*

SIR,—I often wonder how it is our medical literature is published at so high a price. It is so costly that a large portion of it is beyond the possession of a considerable section of the profession. The vast majority of medical men are practically excluded from reading our best standard works on medicine, surgery, and physiology, from their inability or disinclination to pay two, three, or four guineas for a work, no matter what its merits. I know of no other kind of book knowledge that is placed beyond the reach of its aspirants, by virtue of its costliness, so much as medicine and its allied sciences. Take theology as an example. It is published at a price so inexpensive that the million are able to procure it. And all other scientific works are much on a par, and yet they are embellished by diagrams, wood engravings, and illustrations of every kind, which so greatly enhance the cost of production. Sir H. Thompson has set a good example in issuing a cheap edition of his lectures on urinary disorders, and one worthy of imitation. I have no doubt it is proving highly remunerative. If authors would bring out their works in a reasonably cheap form they would soon find their productions give them better pecuniary results, and their publishers would not be hampered by having their shelves burdened with slow-selling or unsold editions, which ought to be lying on the shelves of professional private libraries. There are hundreds of works unread which those of us who do not belong to a Medical Society library never can peruse because we cannot afford to purchase them. I know of no solid reason why this state of things should continue. It would be invidious to single out any work of high merit as an instance of costliness, but if we cast our eye over the advertisement pages of THE LANCET, or glance at such a list as Churchill's, we see numberless cases establishing my proposition. In one list of Churchill's books, advertised in Gowers' "Diseases of the Spinal Cord," I find the value of the books therein announced is over £150, and it is stated to be only a selected list. To form a good medical library one would have to spend a small fortune, and yet it is expected we all should know something of every work sent out. Those of us who wish to be abreast with the current literature are supposed to read the leading books as they appear, and to be well informed this becomes almost an absolute necessity. There is an ever-recurring

change in our views, and new features and opinions are cropping up with a rapidity perfectly marvellous, if not appalling. Let all, then, have a chance of obtaining knowledge by placing within the reach of all the treatises which supply it, and I warrant thousands of books will be bought in place of one now at the exclusive price they are published.

Let me urge you, Sir, as THE LANCET is the acknowledged organ of the profession, to take this question up seriously; and I doubt not you will soon so influence opinion amongst authors and publishers that a new order of things will prevail, and you will thus confer a lasting benefit on the medical world.

I am, Sir, yours truly,  
 Southport, Aug. 3rd, 1882. G. B. BARRON.

## "SALICYLIC SILK."

*To the Editor of THE LANCET.*

SIR,—Dr. McGill finds fault with me for saying that the mackintosh was used at Leeds even with the salicylic silk. I am sorry if I have been incorrect in my statement, but my authority is the paper of Mr. W. H. Brown, which I mentioned. He says: "I place over the wound a piece of gauze soaked in five per cent. solution of carbolic acid; then surround the wound with a double handful of salicylic silk; over this I put the gauze and mackintosh pad, and bandage in the ordinary way."—Yours faithfully,

J. LOCKHART GIBSON, M.B., C.M.  
 Edinburgh, August 7th, 1882.

## NOTIFICATION OF INFECTIOUS DISEASE.

*To the Editor of THE LANCET.*

SIR,—This town being one of those in which the Notification of the Infectious Disease Act is in force, on June 6th I certified to the medical officer of health that F. W. — was suffering from scarlet fever. The nuisance inspector visited the house, forbade the patient's father, a cabdriver, to ply for hire, offered him employment in the town's service (which, unfortunately, he was unable to perform), still living and sleeping at his own house, and gave him leave to ply again on the 18th (desquamation commenced about the 14th, and was not complete on the 28th). He paid another visit on June 17th, in consequence of which, on June 20th, I wrote a letter, of which the following is a copy, to the Sanitary Committee:—

"Gentlemen,—I found this morning that the sanitary inspector had visited a house wherein I have a patient suffering from scarlet fever; that he had given the mother a prescription, and exacted a promise from her that the same would be taken to Mr. —'s (chemist) shop, where the accompanying bottle and contents were received. He had directed that my patient be bathed or sponged, and afterwards rubbed with the contents of the said bottle. Now, I request to be informed by whose authority your servant (whom I believe to be ignorant of any knowledge of the practice of medicine) has thus ordered and prescribed for a patient of mine. If this were done by a medical practitioner, it would merit severe condemnation, as ungentlemanly and unprofessional, but if practised by a nuisance inspector, some of the members of your body know may simply mean murder at no very distant date."

This letter was read at the meeting on June 21st, and, although there was another ordinary meeting on July 19th, I have not received any reply; and yet I think five minutes' examination would enable the Sanitary Committee to say whether they themselves, the medical officer of health, or the nuisance inspector was the authority. On the 20th, after writing the above letter, the inspector called on me, bringing the prescription, in the handwriting of the medical officer, which I quote from memory:—"For the Corporation. R. Ol. communis fl. 3 viii., acid. carbol. 3 ii. To be used &c. For scarlet fever patients." The inspector told me that before directing the mother he had asked her if I had given over attending the case, and that the mother had answered "Yes," which I told him entirely altered my view of the matter; and if he had so done, as he said he was sorry for having interfered, I promised to withdraw my letter. But next day the mother and her sister gave me a written statement, duly signed, that the inspector did not even ask the question, and circumstantial evidence bears her out; for

on the 17th she told a neighbour that I was going to call again, and F. W.—on that day could not walk, if stand. I therefore did not withdraw my letter.

I and my colleagues wish to know if this is the usual manner in which the confidence of medical practitioners is abused who work under the above-named Act, and shall be glad to have your opinion on the matter.

I am, Sir, yours truly,

Blackpool, August 4th, 1882.

R.

## DEATHS FROM ANÆSTHETICS.

To the Editor of THE LANCET.

SIR,—Having observed at various times in the medical journals accounts of deaths from the effects of the administration of anæsthetics (chiefly chloroform), and the measures adopted to rescue the patients' lives, I have been much surprised to find that no mention has been made of the hypodermic injection of the ordinary anæsthetic ether, possibly because, I presume, this has not been adopted. I believe a drachm may be regarded as a moderate quantity, and may be followed by the like dose five or ten minutes afterwards if necessary. I do not claim any originality for the suggestion, but merely wish to more widely circulate the fact, for I have seen this treatment resorted to on several occasions, invariably with marked success, even when others, such as artificial respiration, electricity, &c., have failed—indeed the only death I have seen from the effects of an anæsthetic was in a case where the hypodermic injection was not used.

In conclusion, I may mention that it is advisable to use a larger syringe than those ordinarily used for the injection of morphia, and to have a sliding piston instead of a screw.

I am, Sir, yours truly,

Baron's Court, S.W., July 31st, 1882.

R. FITZROY BENHAM.

## DURHAM UNIVERSITY.

(From a Correspondent.)

THE Jubilee of this University was celebrated at Durham most successfully in the last week of June in various ways. A beautiful heraldic window has been erected in the magnificent hall of University College. The new University Buildings on Palace-green came into use in the early part of this year.

On June 27th, at Convocation a large number of honorary degrees were conferred on noblemen connected with the north of England, and men distinguished in the sciences and arts. Amongst those who received the honorary D.C.L. were George Yeoman Heath, M.D. Dur., President of the College of Medicine, and G. H. Philipson, M.D. Dur., F.R.C.P., the Professor of Medicine. In the evening of the same day a grand concert was given by members of the University in the new buildings.

Thursday, June 29th, was the great day of the Jubilee week. University services were held in the cathedral, and in the evening a dinner in the great hall of University College, when the Warden of the University, the Very Rev. W. C. Lake, D.D., Dean of Durham, announced that the Bishop of Durham and the Visitor of the University would that day place at the disposal of the University £1000 for the purpose of founding a scholarship in memory of his predecessor, the great promoter of literature, Richard de Bury.

The number of students in this the fiftieth year of the University's foundation is as follows: University College, 111; Bishop Hatfield Hall, 110; the College of Medicine, 127; the College of Physical Science, 82; unattached students, 72. The total number of members of the University is 2118.

## GLASGOW.

(From our own Correspondent.)

AT the last meeting of the managers of the Royal Infirmary the vacancies on the Dispensary staff were filled up by the appointment of Drs. J. Wallace Anderson, J. Dougall, D. Campbell Black, Brock, and Shaw to the various posts.

There was a warm contest, and most of the candidates canvassed very freely.

I notice that the Executive Committee of the Southern Hospital, having secured an excellent site, invite architects' plans for a hospital of 120 beds, the cost not to exceed £20,000. A premium of £50 is promised for the best design. It is just possible that the Committee may lose the fine site they had arranged for, as some of the members of the Town Council profess to have discovered that in parting with the ground at a merely nominal sum the Council acted illegally, being formally bound to obtain the ordinary market value for all land sold. If this be so, it will be a serious matter for the proposed hospital, as it will add about £10,000 to the £5000 already agreed upon.

Dr. J. B. Russell, in his health report of a fortnight ago, made some interesting statements regarding the use of "turned" milk for children. He points out that while the death-rate from lung affections had fallen considerably, that from diarrhoeal affections among children had risen as high as during the very warm, dry summer of 1880, and this, notwithstanding the recent moderate temperatures and excessive rainfall. The prevalence of diarrhoea may be fairly ascribed to the changes effected in milk by the electrical disturbances so frequent here of late, the majority of deaths having probably occurred among what we know as "bottle babies." Dr. Russell enjoined the greatest care on the public in the keeping of milk and of feeding bottles.

## SCOTTISH NOTES.

(From our Correspondent.)

INVERNESS is at present suffering from a scarcity of water, which must be most disappointing to those who favoured the gravitation scheme a few years ago. It was carried out at a large cost, and Loch Ashie was believed to be capable of supplying the town abundantly. It is not quite clear from what cause the present scarcity has arisen, and the subject is now under the anxious care of the authorities. Rumour has it that the quality of the present water is most questionable, and it will be expected that a town with such a tourist traffic will raise itself above suspicion in this important matter.

A large number of newspapers, received from Perth and Dundee, show the great interest at present existing in the former town regarding its sanitary state. It would appear that during last winter a course of health lectures was delivered by the local medical men in Perth, and that in one of these, on "Epidemics," Mr. Trotter, L.R.C.P. Ed., passed some very severe strictures on the condition of the town, particularising many matters and places, which he alleged were in a disgraceful state, and wondering that epidemics were ever absent. Much of this had often been said before, but the forcible language of Mr. Trotter roused the indignation of the authorities, and they denounced him in unmeasured terms, denying his statements by their own and the mouth of their medical officer, Mr. Simpson, M.B., *in toto*. An inspector from the Board of Supervision, attracted by the lecture and its discussion, paid Perth a visit, and his report in all essential matters bore out the justice of the outside criticism, both with regard to the insanitary state of the town and the unsatisfactory source of the water-supply, which is taken from the Tay after it receives the whole sewage of the town, and of many other villages on its banks. The authorities, again faithfully backed by their medical officer, next reply in their former manner to the strictures of the inspector, and Mr. Simpson writes a report. I notice that the newspapers commenting on the subject think Mr. Trotter more deserving of thanks than censure, but as the discussion has now come down to personalities, it may be pointed to as a fair example of "how not to do it." Let us hope that both sides may cool in their criticism of each other, and unite to bring about a better condition of matters in the "Fair City."

The presentation to Mr. Sinclair, M.B., Aberdeen, mentioned by you last week, was richly deserved, as he, with great enthusiasm and success, organised a class at the Infirmary for practical work. No fee was charged to the student, and this is nowadays something to be noted.

## PARIS.

(From our Paris Correspondent.)

HERNIA is a much more common infirmity than is generally supposed. A well-known "bandagiste" or truss maker in Paris has drawn up a statistical table comprising a period of fifteen years, from April 1st, 1865, to April 1st, 1880. According to this report, he had during that period 53,489 applications for trusses for both sexes, which he has classified as follows:—

	Men.	Women.
Inguinal hernia (simple) . . .	32,866	928
Inguinal hernia (double) . . .	8637	419
Femoral hernia (simple) . . .	177	1726
Femoral hernia (double) . . .	205	925
Umbilical hernia . . . . .	1935	2782
Ventral hernia . . . . .	88	411
Other herniæ . . . . .	1276	711
Double herniæ . . . . .	343	60
	<u>45,527</u>	<u>7962</u>
	53,489	

From the above table it will be seen that inguinal herniæ, which are more frequent in men, are rarely found in women; femoral herniæ, on the contrary, may be said to be peculiar to women; and it was for this reason that our forefathers gave it the name of "woman's hernia." The great disproportion between the number of herniæ in men, and the number of the same nature in women, is due to the anatomical construction of the pelvis, which is so essentially different in the two sexes. It may be observed, also, that umbilical and ventral herniæ are very frequent in women who have borne a number of children, and particularly when they become pregnant at short intervals.

Since the abolition of the "Tours" or foundling hospitals infanticides have become much more common in this country. During last month two cases were tried at the Court of Assizes for this abominable crime. One was for the murder of a new-born infant by its mother, a young girl who had been seduced. The crime was effected by the child being thrown down the pipe in the privy leading to the cesspool. The mother got off with "extenuating circumstances," as the medical man called in to give evidence gave a certificate to the effect that the child was so small, it having only reached the eighth month of intra-uterine life, that it could easily have slipped through the opening in the pan without the employment of force, and it bore no marks of violence. It was, however, proved that the child was born alive, but that its death might have been caused by congenital weakness.

The next day another case was brought before the Court of Assizes for the same crime. Here also the heartless mother resorted to the same means as the above; but the child, which was at full term, could not get lower down than the circular opening of the pan, where its head was engaged, and some of the lodgers passing by the privy, hearing the cries of an infant, opened the door, and saw the feet of a child, which was evidently struggling for life, with its head downwards. A medical man was immediately sent for, and he soon extricated it from the perilous position alive. Notwithstanding the persistent denial of the accused of her intention of putting an end to the child's life by the means she had recourse to, pretending that the child had escaped from her while she was at stool, there was sufficient evidence to show that she fully determined to put the atrocious act into execution. She was in consequence, in spite of the "extenuating circumstances" that were allowed her, condemned to hard labour for life.

Only on Saturday last, a domestic servant, who had concealed her pregnancy and done her work to the moment she was taken in labour pains, retired to her own room and there went through the process of parturition without her neighbours having the least suspicion of what was taking place. As soon as the child was born (alive) she strangled it and concealed it under her bed. After the horrible crime was accomplished she attempted to resume her work, but was unable to undertake it; and her mistress, finding that she looked so ill, desired her to return to her room, to which she accompanied her, and, discovering the dead child, the servant, of course, made a full confession of what had taken

place. The lady immediately made a report of the circumstance to the police, and an inquiry has been instituted.

A batch of savages has just been brought over from Maroni, in Guiana, and are quartered in the Jardin d'Acclimatation. They are fourteen in number, consisting of an old mother (whose age is unknown), a grown-up girl (who seems somewhat civilised), three boys from eighteen to twenty years of age, two young mothers of fifteen and sixteen each, with a suckling baby and seven other children. Their legs are tattooed, and their upper lip is also tattooed in the form of a moustache, the lower lip being pierced through with a thick pin, which serves as an ornament. The Comte de La Grange, who brought them over, also brought with him some specimens of earthenware, which are very interesting and curious. Their habits are very simple; but they object to eating before strangers. Their only clothing consists of a sort of bathing drawers reduced to its simplest expression. The seven children are very handsome; their features are regular, their complexion slightly copper coloured, and were it not for their tattooing and their complete nudity, they would at first sight be taken for Bohemian gipsies.

Dr. Pidoux died on the 4th inst., at his residence in Paris, from diabetic gangrene. He was more than an octogenarian, took his degree in 1835, and has been a member of the Academy of Medicine since 1864. Dr. Pidoux has written a great deal; but his principal work is his "Traité de Thérapeutique et de Matière Médicale," the first edition of which was published in 1839, in conjunction with the late Dr. Trousseau. He was for a long time principal physician at the Eaux-Bonnes, and was a great authority on matters connected with the therapeutic action of sulphurous waters. He was also Officier of the Legion of Honour.

Paris, Aug. 8th, 1882.

## NEW YORK.

(From our own Correspondent.)

I HAVE the pleasure of stating that all arrangements for the opening of the New York Post-Graduate School of Medicine, on November 1st next, are now complete, and, with the exception of one chair, the Faculty is named. I consider this will be one of the most interesting events in the annals of medicine on this continent, and will mark a new era in regard to medical education. Arrangements had been made for the opening of such a course in connexion with the Medical School of the College of the City of New York, but a programme agreeable to all could not be submitted, and those most interested in the success of the movement resigned their positions and determined on independent action, the result of which is the inauguration of the new school of medicine in Twenty-third-street, New York City.

The Faculty will comprise the following eminent physicians, who are all accomplished specialists, in the department of medicine over which they will preside:—James W. Little, M.D., Professor of Clinical and Operative Surgery; Wm. A. Hammond, M.D., Professor of Diseases of the Mind and Nervous System and Medical Electricity; D. B. St. John Roosa, M.D., Professor of Diseases of the Eye and Ear; Henry G. Piffard, M.D., Professor of Diseases of the Skin; Frederick R. Sturgis, M.D., Professor of Diseases of the Genito-urinary Organs and Venereal Diseases; M. A. Pallen, M.D., Professor of Diseases of Women and of Operative Midwifery; Thomas E. Satterthwaite, M.D., Professor of Histological and Pathological Anatomy; Mary Putnam Jacobi, M.D., Professor of Diseases of Children; E. C. Spitzka, M.D., Professor of Medical Jurisprudence and State Medicine; William J. Merton, M.D., Associate Professor of Diseases of the Mind and Nervous System; Herbert G. Lyttle, M.D., Associate Professor of Genito-urinary Diseases; William H. Porter, M.D., Associate Professor of Histological and Pathological Anatomy; Edward T. Ely, M.D., Associate Professor of Diseases of the Eye and Ear; W. Ward, M.D., Associate Professor of Diseases of the Throat; W. T. Alexander, M.D., Associate Professor of Diseases of the Skin.

No undergraduates will be admitted to this College, it being opened for physicians only, the idea being not to in-

crease the number of doctors, but to raise the standard of medical knowledge among those already in practice. The course of study will be by clinics and demonstrations in contra-distinction to the lectures given at other medical schools.

In looking over the names of the faculty your readers will notice that of a woman, Dr. Mary Putnam Jacobi. I believe this to be the first instance of a lady being elected to a professorship in a medical school. Whatever opinion may be expressed respecting this innovation, there can be but one as to the fitness of this lady for the position in question. Dr. Mary P. Jacobi's skill in treating the diseases of children is acknowledged by the medical profession, and her instruction in this department will be a welcome addition to the excellent course of study which will be provided.

The opening of the New York Post-Graduate School of Medicine is the outgrowth of a movement which has been at work for some years. The medical profession has been aware that the course of instruction provided for graduates of medicine was totally inadequate, and that the majority of those taking their degrees were unfit to practise medicine. All recent efforts to raise the standard of medical education have been abortive, and, with few exceptions, even the extended time for study has been reduced to the old limits. It is four years since I had occasion to look into this subject, when I wrote editorially in the *New York Times*, with the effect of improving the course of study at the medical school of the Johns Hopkins University then about to open. At that time (and I fear the conditions are little changed) I found there were sixty-five medical schools in the United States besides those devoted to homœopathy, eclectic, botanic, and other systems. During the winter of 1866-7 these sixty-five schools had 7141 students, of whom 2313 graduated as Doctors of Medicine in the spring. In only five of these schools was there a graded course of three years, and in only two was a preliminary examination required, and that of a very low grade. Of the remaining schools, I was informed on the best authority, only fifteen could be said to be doing fairly good work, that is to say, as good as there is a demand for. This leaves forty-three medical schools, out of a total of sixty-five, that were doing poor, indifferent work. The course of medical study in the United States is wrong from first to last. In the first instance, the student is supposed to have studied with a private preceptor for one year before he takes his medical course. Surely this is a farce and a waste of time, for when the student should be studying anatomy, chemistry, and physiology, his attention is directed to practical medicine and surgery. I then summed up the defects of the American system as follows: 1st. The absence of a preliminary examination. 2nd. The very short period of the studies required. 3rd. The want of training in the practical branches. 4th. Absence of any grading in the curriculum. 5th. The examination of the candidates for the degree by those having a direct pecuniary interest in their success. The medical schools of New York, Boston, and Philadelphia afford excellent opportunities for making good general practitioners, and only need reforms extending the time of study. Doubtless there are plenty of young men who have sense enough to know that a thorough medical education will pay in the long run in spite of the time and money it costs. To such the new Post-Graduate School in New York City will be a boon, presenting opportunities for completing their knowledge of any particular department of medicine which they consider essential to their future success. From my personal knowledge of many members of the faculty I can testify to their being gentlemen who have offered their services from the best motives, desiring to elevate the profession of which they are distinguished members, and to improve the standard of medical education. I understand the success of the new medical school is assured. It would be a disgrace if it were otherwise.

July 22nd, 1882.

[Our New York correspondent wishes us to request residents in the United States to forward matter suitable for insertion in correspondence to him, addressed THE LANCET, P.O. Box, 3230, New York City.]

THE Birmingham Borough Hospital and offices of the Health Department, three miles away, have had telephonic communication established between them in order to lessen the risk of the spread of infection by friends visiting patients.

## MEDICAL NOTES IN PARLIAMENT.

### *Irish Lunacy Officials.*

IN the House of Commons on Thursday night, the 3rd inst., during the discussion of the Irish votes in Committee of Supply, Mr. Blake complained that two of the inspectors of lunatic asylums in Ireland were too old and decrepit for their duties, and ought to be retired. Mr. Findlater drew attention to the discrepancy between the terms of the retirement of lunacy officials in England and in Ireland, showing that they were much to the disadvantage of the Irish officers. —Mr. Trevelyan, in a general reply, stated that it was his intention during the next four or five months to personally inquire into the constitution and administration of all the public departments in Ireland.

### *Registration of Midwives.*

Petitions in favour of a system of registration of midwives continue to be presented to the House. On Friday three such petitions, and on Tuesday eight, were presented from London, and similar memorials came from Pulborough, Lower Beeding, and Slaughtam.

### *Treatment of Emigrants.*

Mr. Moore drew attention to this subject on Friday, and moved a resolution demanding a revision and reform of the Passenger Acts. He admitted that great improvements had recently been made in accommodation of emigrants on board ship, but contended that much required to be done with regard to their reception and lodgment at the ports. —Mr. Chamberlain said only one of the Atlantic steamship lines had failed to comply with the recent recommendations of the Board of Trade, and that line, he hoped, would not be long recalcitrant. No reform of the law appeared to be required, although a revision of the Passenger Acts might be useful. As to the overcrowding of Scandinavian emigrants at Hull, it was doubtless unsatisfactory; but cases of hardship only occurred during the busiest season. The question of the erection of depôts for their reception was under consideration by some of the companies, but as they could only be used two or three times a year, the general opinion was against the proposal. He thought it better to leave these matters to the voluntary action of the companies, who had expressed their willingness to do anything to promote the health and comfort of the emigrants. —The resolution was negatived.

### *Lunacy Bills.*

On Friday, the Lunacy Districts (Scotland) Bill, which stood for Committee, was withdrawn.

On Saturday, the Lunacy Regulation Bill passed through Committee, and it was read a third time on Tuesday. Some hostility was shown to the measure by Mr. Warton, Sir H. Holland, and Mr. Montagu Scott, on the ground that it proposed to reduce the number of official visits to Chancery lunatics from four to two visits per year, in order to save appointing more visitors. Mr. Hibbert explained that it was only proposed to reduce the visits to lunatics kept in private houses, mostly with friends. There were 400 of these. There were also 800 Chancery lunatics in public or private asylums, and the visits to them were to be increased from one to two per annum. Dr. Farquharson said, those who lived with their friends were harmless lunatics. They did not need frequent inspection, but it was needed in case of lunatics who were only looked after by paid attendants. Mr. Stanley Leighton advocated an increase of the number of visitors, and Mr. Scott denounced the parsimonious system which sought to make money out of the fees levied on account of Chancery lunatics. Eventually the Bill was amended, on the offer of Mr. Hibbert, by making the annual number of visits three instead of two, in regard to private houses.

On Tuesday, Sir W. Harcourt replied to Mr. R. H. Paget that when he had read the report of the Departmental Commission which was appointed in 1881 to consider questions relating to criminal lunatics, and when it had been considered by the Treasury, he would see whether it could be presented to Parliament.

Upon the motion of Mr. Acland, returns were ordered of various details of the cost of the accommodation and maintenance of pauper lunatics.

### *The Norwich Vaccination Inquiry.*

Mr. Taylor, for the third time, put questions to the President of the Local Government Board as to the alleged deaths of

children at Norwich from the effects of vaccination, and Mr. Dodson again replied that he had not yet received the report of the inspector who conducted the inquiry.

#### Sanitary Regulations in Private Bills.

Mr. Selater-Booth moved a new standing order for the guidance of Select Committees on Private Bills. It proposed to lay down several general considerations, one of which was whether a Bill gave to any local authority powers relating to police or sanitary regulations which were in conflict with or in excess of the provisions or powers of the general law. The right hon. gentleman explained that his proposal was the outcome of the recommendation of the Select Committee which sat this year on a group of Private Bills dealing with sanitary and police regulations; but Sir Charles Forster, on behalf of the Government, contended that more time was required for the consideration of the matter, and moved the adjournment of the debate, which was agreed to.

#### Victoria University.

Mr. Mundella stated to Mr. Slagg that the Court of Governors of the Victoria University, Manchester, had determined to petition for power to grant medical degrees. When the petition was received it would be submitted to the Queen in Council. The granting of the prayer of the petition would not be inconsistent with the report of the Royal Commission on the Medical Acts.

On Wednesday, on the motion of Mr. Warton, a return was ordered of the memorials recently forwarded to the Board of Admiralty from inhabitants of Portsmouth and Devonport respecting the working of the Contagious Diseases Acts.

#### Pauper Lunacy Returns.

The order for Mr. Acland's lunacy returns was discharged, and returns in a different form were ordered on the motion of Mr. Hibbert. These returns will show the population and rateable value of the several unions in England and Wales, the number of pauper lunatics chargeable to each union, the cost of the maintenance of such lunatics in asylums and licensed houses, and the amount of the Parliamentary grant in aid of their maintenance; also the extent of the accommodation in each of the several county and borough asylums in England and Wales, with the cost of additions and structural alterations in each asylum.

## Medical News.

UNIVERSITY OF EDINBURGH. — The following is the list of candidates who, having passed the required examinations, received on Aug. 1st the Degrees specified:—

#### DOCTORS OF MEDICINE.

Barrs, Alfred George.	MacLennan, D. Urquhart.
*Bendall, Howard.	*Macphail, S. Rutherford.
Brebnner, George Reith.	Mead, Robert Wm.
†Cameron, R. W. Dickenson.	Oakes, Arthur Wm.
†Chisholm, John Merrit.	Oliphant, Wm. Bruce.
*Croon, John Halliday.	†Renton, Jas. Crawford.
Druitt, Lionel.	†Ross, Joseph Carne.
Purley, Wm. Grant.	Shaw, William.
Guillemard, Bernard J.	†Smith, G. Daniel.
Handford, Henry.	*Stuart, T. Peter Anderson.
†Hope, Edward Wm.	*Taylor, Herbert Coupland.
Hutchinson, E. De Warren.	†Thom, Alexander.
†Leeson, John Rudd.	†Thomson, James.
†Le Fevre, George.	†Tunstall, A. Croudson.
†Mackenzie, James.	Watson, Chas. Scott.
†M'Lean, Chas. Alex.	*Wilson, Albert.

#### BACHELORS OF MEDICINE AND MASTERS IN SURGERY.

Aitchison, R. Swan.	Brewis, Nathaniel T.
Aitchison, Thomas.	Bryant, Sidney Wm.
Archer, Leonard Thomas	Buchan, W. Augustus.
Fitz Samuel.	Burn-Murdoch, Geo.
†Ashdown, Herbert Harding.	Bury, Percy Bellamy.
*Ashwell, Frederick.	Calvert, Wm. Hall.
†Atkinson, G. Armstrong.	†Campbell, Saml. G.
Bailey, Thos. Ridley.	Charlesworth, Francis.
Baillie, Peter.	†Christie, Arch. Kennedy.
†Basil, Minas Manook.	Clayton, J. Simpson.
Basu, Basanta Kumar.	Closs, J. Osborne.
Bell, G. J. Hamilton.	Cousland, P. Brunelleschi.
Bell, Horace Lynden.	Davidson, J. Henry.
Benjafield, W. Barnett.	Davies, John.
Bolton, J. Shepherd.	*Delepine, Auguste Sheridan.
Bond, J. H. Richard.	†Dickson, Geo. Cecil.
Borrowman, P. Grierson.	Dobie, John Robt.
Boswell, H. St. George.	Duckett, John Wilson.
Bourne, C. Harper.	Dumas, Henry Aylmer.
†Bowie, John.	Dunlop, Robt. Smith.
Bowman, Alistair Stuart.	Dutton, Wm. Henry.

Fletcher, Henry Jas.	Mead, Rivas.
Forbes, Alexander.	Meggison, T. Cockburn.
Fraser, Alex. Ross.	Mickle, A. W. T. Flintoff.
Fraser, Elias.	Mill, A. J. Macket King.
†Fraser, Thos. Alex.	Mills, Bernard Langley.
Galletly, Geo. Wilson.	Moore, A. Malcolm.
Gay, William.	Morgenrood, E. H.
Gifford, Lawson.	Mouncey, Chas. Jas.
Gilbert, Herbert Jas.	Murray, R. Ulysses W.
Giles, Wm. Anstey.	Myrtle, Jas. Aitken.
Gillison, Thomas.	Nash, John Brady.
Godfrey, Joseph Edw.	Neale, Alfred James.
Graham, James.	Neve, Ernest Fredk.
Grant, Francis W.	Oliphant, Eben. H. Lawrence.
Grant, Henry Lewis.	Patner, Edmund Stuart.
Grant, John.	†Paterson, G. Kipple.
Grant, Wm. Francis.	*Paton, Diarmid Noel.
Greenlees, T. Duncan.	†Paton, Fredk. Erskine.
Griffin, John.	†Philip, Robt. Wm.
Gunn, Clement Bryce.	Philip, Thomas.
Guthridge, G. Fredk.	Phillips, J. Randal.

#### MASTER IN SURGERY.—Howard Bendall.

The following Prizes &c. were also awarded:—

ETTLER PRIZE.—George Armstrong Atkinson and Sidney Johnson Taylor.
BEANEY PRIZE.—George Armstrong Atkinson.
SYME SURGICAL FELLOWSHIP.—Howard Bendall.
BUCHANAN SCHOLARSHIP.—David Smart.
* Obtained Prizes for their Dissertations.
† Deemed worthy of competing for the Dissertation Prizes.
‡ Commended for their Dissertations.
\$ Passed the Examinations with First Class Honours.
Passed the Examinations with Second Class Honours.

UNIVERSITY OF GLASGOW. — At a Graduation recently held the following Degrees were conferred:—

#### DOCTORS OF MEDICINE.

*Adams, Thos. B., M.B.	Pollock, Chas. F., M.B.
Guthrie, Thos. Orr, M.B.	*Raukin, Guthrie, M.B.
Halket, Geo., M.B.	Taylor, David, M.B.

#### ROYAL COLLEGE OF SURGEONS IN IRELAND.—

At the July examinations the following obtained the Licence in Surgery of the College:—

James Tandy Bolger, R. H. Coall, Austin Nathaniel Cooper, Percy Herbert Delamere, Bernard Joseph Dillon, Myer Akiba Dutch, John Peter Garland, Arthur Joseph Greene, Alfred Adolphus Hayes, John Colclough Hoey, Timothy Howard, James Lane, Joseph Lalor, John Michael M'Donagh, William M'Gee, James M'Guire, Frederick Joseph M'Naught, Edward Duddy Mullan, Percy Newell, Michael Joseph Nolan, Thomas O'Connell, William Edmond O'Connor, Rowland Pollock, John Turner Power, Francis C. Roe, Robert Corles Sanders, Michael Patrick Sweeny, William Christopher Thompson, John Joseph Todd, Edward W. Wynne.

**APOTHECARIES' HALL.**—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on Aug. 3rd:—

Blagg, Arthur Frederick, Crowndale-road, Oakley-square.  
 Brown, James William Henry, Kirkdale-road, Leeds.  
 Davis, James Warren, Tu Warren, Milford Haven.  
 Dean, Francis, Overstone-road.  
 Herron, James, Kingsland.  
 Hubbard, Arthur John, Ladbroke-terrace, Notting-hill.  
 Lister, Joseph Herbert, Huntley-street, Bedford-square.  
 Williams, Robert, Amlwch, Anglesea.

The following gentleman also on the same day passed the Primary Professional Examination:—

Guilding, Lansdown M., Middlesex Hospital.

[In the list of gentlemen who obtained the Membership of the Royal College of Surgeons of England on the 27th ult., the third name should have been Downman, not Dowman.]

**THE Royal Hospital for Incurables, Putney,** has received a donation of £30 from the Queen.

**BUTTERINE.**—A Dublin trader was fined £5 last week for selling this compound instead of butter.

**AN anonymous benefactor** has given £500 to the Yeovil District Hospital.

**A MARBLE bust** of the late Mr. Frank Buckland has just been placed at the entrance to the Fish Museum, South Kensington.

**VACCINATION GRANT.**—Mr. Edward East has received the Government grant for efficient vaccination in the Swinefleet district of the Goole Union (second time).

**SALE OF POISONS ACT.**—At the Clerkenwell Police Court last week a druggist was fined £5 and costs for selling laudanum without attaching to the bottle a label bearing the name of the seller.

**ST. JOHN AMBULANCE ASSOCIATION.**—Male and female classes have this week been opened in the Royal Engineers' Institute, Chatham, by Lieut.-Col. F. Duncan, R.A. Surgeon-Major Muir, of the Army Medical Department, has consented to give the lectures. At the opening of the male class, a number of men under orders for Egypt were present, and received some useful hints as to the first treatment of the wounded.

**SANITARY INSTITUTE OF GREAT BRITAIN.**—At the Congress to be held at Newcastle-on-Tyne from September 26th to 30th, Dr. Richardson, F.R.S., has consented to give a lecture to the working classes. The exhibition in connexion with the Congress will remain open until October 21st.

At the first annual meeting of the members of the Mile-end Old Town Victoria Park Hospital Association, it was announced that the efforts put forth during the past year had resulted in the addition of fifty guineas to the funds of the hospital.

**UNIVERSITY OF EDINBURGH.**—Mrs. Thomson of Rosalee, Hawick, has intimated to the Senatus of the University of Edinburgh the foundation by her of a scholarship in midwifery, to be called the James Scott Scholarship, in memory of her father, the late James Scott, of Allanshaws. This is the second scholarship in the same department for students of this university, Mrs. Buchanan, of 49, Moray-place, Edinburgh, having two years ago provided funds for a scholarship in gynecology. In both cases the scholars receive the yearly interest of £1000.

**NORTH OF SCOTLAND MEDICAL ASSOCIATION.**—At the annual meeting of the members of the above Association on the 29th ult., Professor Pirrie delivered an address on the Infectiveness of Tubercle, printed in *extenso* in THE LANCET last week. Dr. Pirrie, Dr. Struthers, Dr. Rodger, Dr. Beveridge, and Dr. Lyon were appointed a committee to co-operate with a committee of the Glasgow Association to endeavour to obtain the removal or relaxation of the present restrictions on the performance of vivisectional experiments. Dr. Manson of Banff was nominated President elect.

**THE TECHNOLOGICAL, INDUSTRIAL, AND SANITARY MUSEUM OF NEW SOUTH WALES.**—The Colonial Government are making rapid progress with the organisation of this museum, which has now been permanently established in the Garden Palace at Sydney, the building in which the International Exhibition of 1879 was held. Arrangements are now being made for the shipment of contributions to the museum from manufacturers in this country, which for the most part consist of sanitary appliances and articles connected with building. These contributions are being forwarded to Sydney free of cost by the Government on the recommendation of the British committee, at the head of which is Sir Saul Samuel, the Agent-General for the Colony. This committee have issued a circular in which they say the Sydney Museum occupies a similar position, and fulfils the same purposes in New South Wales, as the South Kensington Museum and the Parkes Museum of Hygiene do in London. Large numbers of houses are being erected in the City of Sydney and other cities and towns of the Colony, in one suburb alone six hundred houses having been built last year. Moreover, the authorities are paying great attention to sanitary matters, and the principal object of the Government in establishing and maintaining the Museum is to provide a means whereby the Colonists may become acquainted with improved apparatus and appliances for building and domestic purposes. Mr. Mark H. Judge (8, Park-place Villas, Paddington) is the acting member of the British committee for forms, &c.

## Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning at the latest.

ANTHONY, JOHN, L.R.C.P.Ed., L.F.P.S.Glas., has been appointed Medical Officer for the Arncliffe District of the Settle Union.  
 BERNARD, ALFRED G. FARQUHAR, M.R.C.S. & L.S.A.Lond., has been appointed Medical Officer to the Troops at the Seaforth Battery, vice Dr. C. Swaby-Smith, resigned.  
 CANE, FRANCIS EDWARD, L.R.C.S.Ed., L.R.C.P.Ed., has been elected Resident Dispensary Surgeon to the Bradford Infirmary and Dispensary.  
 CRESSWELL, NATHANIEL ENGELHEART, M.D. St. And., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer of Health for the Towcester Rural Sanitary District, vice Thompson, resigned.  
 DAVIES, R. H., F.C.S., has been reappointed Public Analyst for the Fulham District.  
 JONES, RICHARD, M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer of Health for the Flint Urban Sanitary District.  
 LILLEY, G. HERBERT, M.D., M.R.C.P.E. (late Assistant-Surgeon), has been appointed Medical Officer to H.M. Convict Prison, Portland, vice H. F. Askham, Esq., resigned.

MURIEL, CECIL, L.R.C.P.Lond., M.R.C.S., has been appointed Resident Medical Officer to the Guest Hospital, Dudley, vice R. Walford, M.R.C.S., resigned.

ORR, HUGH, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Filey District of the Scarborough Union.

PATTEN, CHARLES ARTHUR, L.R.C.P.Lond., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Princess Helena College, Ealing.

PERCIVAL, GEORGE HENRY, M.B.Lond., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer of Health for the Northampton Rural Sanitary District, vice Haviland, resigned.

ROLSTON, JOHN R., L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Morice and St. Aubyn District of Stoke Damorel Parish.

SPENCE, WILLIAM JAMES, L.R.C.P., L.R.C.S., has been appointed House-Physician to the Bradford Infirmary, vice Foster, resigned.

STEELE-PERKINS, GEORGE, M.B., C.M.Ed., M.R.C.S., L.R.C.P.Lond., has been appointed Medical Officer to the Port of Exeter.

WHITTLE, EDW. GEO., M.B.Lond., F.R.C.S.Eng., has been appointed Medical Officer to the Waterloo Lodge of the Manchester Unity of Odd Fellows, Brighton, vice Passmore, resigned.

WILLIAMS, ROBERT, M.B., C.M.Ed., has been reappointed Medical Officer of Health for the Leominster Urban Sanitary District.

## Births, Marriages, and Deaths.

### BIRTHS.

BROOMHEAD.—On the 1st inst., at Barker-street, Oldham, the wife of Charles Broomhead, M.D., of a son.

CRAWFORD.—On the 30th ult., at 5, St. John's-park, Blackheath, the wife of Dr. Crawford, Director-General, Army Medical Department, of a son.

HALL-MORE.—On the 3rd inst., at Beachlands, Walmer, the wife of Robert Hall-More, M.D., Staff-Surgeon, Royal Navy, H.M.S. *Scyllaure*, of a son.

LEITCH.—On the 6th inst., at Park-terrace, Sillith, the wife of John Leitch, M.B. & C.M.Ed., of a son.

MCCLEURE.—On the 7th inst., at Verandah House, Worle, Somersetshire, the wife of Thomas McCleure, M.D., F.R.C.S.I., of a son.

PURVES.—On the 2nd inst., at Stratford-place, Oxford-street, W., the wife of W. Laidlaw Purves, M.D., of a daughter.

VIVIAN.—On the 25th ult., at Chase Side, Southgate, N., the wife of R. T. Vivian, M.R.C.S., of a son.

WALL.—On the 7th inst., at Bishop's-road, Bayswater, W., the wife of Reginald Bligh Wall, M.R.C.S., of a daughter.

### MARRIAGES.

BAUMLER-REIMER.—On the 3rd inst., at St. Luke's, Berlin, Christian G. H. Baumler, M.D., F.R.C.P.Lond., Professor of Clinical Medicine in the University of Freiburg, in Baden, to Maria Victoria Reimer, daughter of Dietrich Reimer, Esq., of Berlin.

CORTIS-BRUCE.—On the 3rd inst., at St. Mark's, Kennington, Herbert Liddell Cortis, M.R.C.S. (son of Dr. Cortis, of Kennington-park-road), to Mary, daughter of James Bruce, Esq., of Stockwell-road (late of Cape Town).

DOWDING-TURNER.—On the 26th ult., at Rochdale, by special licence, Alexander W. Woodman Dowding, M.D., M.R.C.P., of Durham House, Barking-road, E., to Florence, the only daughter of David Turner, of Castlefield House.

LEIGH-GEERE.—On the 3rd inst., at the Parish Church, Brighton, Thomas Leigh, L.R.C.P.Lond., to Georgina, fourth daughter of the late George Geere, Surgeon, of Brighton.

NOBLE-THOMPSON.—On the 2nd inst., at Barras-bridge Presbyterian Church of England, Newcastle-upon-Tyne, by the Rev. R. Noble (uncle of the bridegroom), assisted by the Rev. Geo. Bell, James Black Noble, M.R.C.S. &c., of Trinity-square, S.E. (second son of the late John Noble, F.E.I.S., of Newcastle), to Jennie, second daughter of the late Joseph Thompson, of Walker, Northumberland.

WALLIS-WATSON.—On the 3rd inst., at St. Anne's Church, Wandsworth, by the Rev. Benjamin Whitelock, M.A., assisted by the Rev. Edward W. D. Chave, Vicar, William Wallis, of Groombridge, elder son of William Wallis, of Hatfield, Sussex, to Marian Bravery, youngest daughter of Thomas Simons Watson, of The Gables, Wandsworth-common.

### DEATHS.

ADAMS.—On the 29th ult., at Queenstown, Ireland, Andrew Leith Adams, M.D., F.R.S., LL.D., Professor of Natural History, Queen's College, Cork, second son of the late Dr. Francis Adams, Banchoy-Ternan.

BOURNE.—On the 16th ult., at his residence in Howard-street, North Shields, William Bourne, M.D., aged 60.

CHADWICK.—On the 28th June, 1882, at Darling, Cape of Good Hope, Ada Mary, the beloved wife of George T. Chadwick, L.R.C.P.

GELL.—On the 2nd inst., suddenly, at his residence, Southam, near Rugby, Alfred Scott Gell, M.R.C.S., aged 48.

MILLER.—On the 7th inst., James Miller, M.D., of Aberdeen House, Great Percy-street, W.C.

MOGG.—On the 28th ult., at Great Smeaton, Joseph Wm. Oliver Mogg, L.R.C.P.Ed., L.R.C.S.Ed.

POULTON.—On the 31st ult., at Elgin-crescent, Notting-hill, Deputy Surgeon-General Charles Walter Poulton, M.D., eldest son of Joseph Chancellor Poulton, of Cricklade, Wilts, aged 59.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

### BOOKS ETC. RECEIVED.

BAILLIÈRE, TINDALL, & COX, London.  
A Concise Handbook of the Laws relating to Medical Men. By James Greenwood, of the Inner Temple, Barrister-at-Law. Together with a Preface and a Chapter on the Law relating to Lunacy Practice. By L. S. Forbes Winslow, M.B., D.C.L.Oxon. pp. 214.

BLACK, A. & C., Edinburgh.  
Lectures on Surgery. By James Spence, F.R.S.E. Third Edition. In 2 vols. pp. 1126, with numerous Plates and Woodcuts.

CHAPMAN & HALL, London.  
Health Resorts and their Uses. By I. Burney Yeo, M.D. pp. 316.

CHURCHILL, J. & A., London.  
A Treatise on Human Physiology. By J. C. Dalton, M.D. Seventh Edition. pp. 722, with 252 Illustrations.  
Eastbourne as a Residence for Invalids and Winter Resort. By Geo. Moseley, F.R.C.S. pp. 70.  
Therapeutical Remembrancer. By J. Mayne, M.D. Second Edition, revised. pp. 103.

DAWSON BROTHERS, Montreal.  
A Rational Materialistic Definition of Insanity and Imbecility. By Henry Howard, M.R.C.S.Eng. pp. 145.

## Notes, Short Comments, and Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*We cannot prescribe, or recommend practitioners.*

*Local papers containing reports or news-paragraphs should be marked.*

*All communications relating to the editorial business of the journal must be addressed "To the Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

### CHEAP MEDICINE AT SALFORD.

THE following handbill was put into the hands of a practitioner, who forwards it to us. What is to become of the profession when medicine and advice and a speciality are all to be given for a shilling a week!

"Private Dispensary, 91, Oldfield-road (13 doors from Regent-road). Mr. W. Simpson, Surgeon. Where patients can, on the payment of one shilling, receive medicine and advice for the week. Diseases of women and children particularly attended to. Surgery hours: morning, 9.30 to 12; evening, 6 to 9. N.B.—Dispensary patients to bring their own bottles."

### THE SUNFLOWER.

IN the New York *Medical Record* of July 29th attention is directed to the medicinal virtues of the *Helianthus annuus*, the "passion" flower of the modern aesthete. It is an antiperiodic and a counter-irritant, and the stalk of the mature plant, when dried, forms a good natural mola. The anti-malarial properties of the sunflower were pointed out by Masary in 1859.

Mr. Jenkinson.—They are so considered now by most English pathologists, and doubtless membranous croup should be classed with the zymotic diseases.

### "THE CAUSE OR CAUSES OF ACUTE TONSILLITIS."

To the Editor of THE LANCET.

SIR,—Your correspondent, Dr. Atkinson, has mooted a subject of great practical and scientific interest in calling attention to the etiology of acute tonsillitis. That little immediate notice has been taken of his communication is of course explicable on several hypotheses, which it is unnecessary to specify. It may, however, be remarked that, common as the disease is, a positive assertion of all its causes belongs to the future. The gland, or rather cluster of glands, in question is one of that countless series the functions of which cannot be more distinctly stated at present than by affirming that they probably further metabolism and excretion; and this view is supported by the clinical evidence furnished by another correspondent of yours in a previous number, of the benefit derived from the use of salicylate of soda in some cases. At the meeting of the Esculapian Club, held on Feb. 21st, 1882, I read a paper on the Salicylate Treatment of Rheumatism, in which I discussed the related condition of tonsillitis, and ventured on that occasion to employ two terms for conditions not unknown, explanatory of the etiology of the disease in question, which may be rather startling from their want of euphony, but which, nevertheless, express sufficiently for clinical purposes the imperfect state of our present knowledge of the subject. These were ergozymosis (*ἐργον + ζύμωσις*), or the presence in excess of the products of wear and tear generally, and cacometabolism (*κακός = bad*), or the imperfect metamorphosis of such products and their consequent imperfect elimination. Under normal circumstances the physiological processes of waste, elimination, and repair are harmoniously effected, and the tissues active in such operations have just so much work to do as they can perform. Or, even when special tissues are overworked, vicarious elimination and accentuated repair may obviate diseased action. But when such collateral aids are unequal to the task, the overworked metabolic structure or excretory becomes hyperemic, inflamed, swollen, and mechanically and dynamically productive of constitutional disturbance. Exposure to cold, it may be of a very moderate degree, in an ergozymotic condition, is, in my experience, the most common cause of tonsillitis, but any reason for defective elimination or imperfect repair of waste may be its more or less immediate or exciting cause. An ordinary "sore-throat" without marked tonsillitis is in many instances essentially an hyperemic condition of the ductless submucous glands of the pharynx, due in most cases to ergozymosis and cacometabolism; while the conditions of chronic enlargement of the tonsils and pharyngeal adenoma or adenoid disease, so productive of mechanical irritative conditions and functional disturbances in this neighbourhood, are, I believe, mainly irritative hyperplasias from the presence of im-

perfectly eliminated cacometabolic products. The treatment of the acute conditions referred to, which follows from the above remarks, is the furtherance of elimination by the usual methods, and sufficient nourishment; or in the case of a specific disease, such as rheumatism (as I pointed out in the paper referred to), the use in combination with diaphoretics and evacuant, of salicylate of soda, which probably acts both by checking the production of the ergozymotic cause of the disease and by rendering it more easily eliminated when produced.

I hope on a future occasion to call attention to the far-reaching significance of cacometabolism and to the chemico-physical influence of cacometabolic products on the structural changes in diseased tissues, to the modification by them of vital processes, and to their production of germ pabula, the antecedent condition and prior cause of many so-called germ diseases.—I remain, Sir, yours obediently,

ALEXANDER MORISON, M.D.

The Terrace, Green-lanes, N., August 7th, 1882.

### To the Editor of THE LANCET.

SIR,—Is tonsillitis dependent sometimes on non-articular rheumatism and sometimes upon depression of vital power? I answer unhesitatingly and to each half of the interrogation, "Yes!" What medical man, at once observant and experienced, doubts the validity of the double connexion? About twelve months ago a former patient, who now resides at a distance of several miles from my abode, wrote: "For many weeks I have been tormented with severe cough, cold, and sore-throat. A fortnight since rheumatism attacked my legs, and my chest symptoms disappeared as though by magic." In 1852 I was acquainted with a medical apprentice whose lines had fallen in places that proved to be the opposite of pleasant. The outcome of the triple infliction of hard work, close confinement, and unceasing heart-stabs was an attack of quinsy.

And now for a word on that much ventilated subject, the cure of tonsillitis. Years since I attended a carpenter who experienced an attack of the disease under consideration regularly every spring. One March his quinsy failed to put in its accustomed appearance. The result was the superintention of prolonged tonsillitis, laryngitis, tracheitis, and bronchitis. A return of the quinsy, however, relieved him, after months of suffering, from further annoyance. For a lengthened period I have been occasionally consulted by an individual aged about forty-five who suffers somewhat severely from tumefaction of both hard and soft palates, plus oedema of the uvula and lining membrane of the larynx and upper portion of the trachea. In happier times, now long since gone by, he underwent frequent attacks of tonsillitis, several of which terminated in abscess. In 1882 the burden of his threnody is, "Oh, that I could have quinsies over again!" Individually he would as soon attempt to suspend the pains of natural labour as to abort a tonsillitis. In my opinion acute disease is an entity which the practitioner will do well to assist to a natural termination—by no means a something that he should pounce upon—strangle in its birth. What a pity it is that medical men exhibit their present indisposition to report leading cases. Every man can write intelligibly, though to play gymnastics with the Queen's English is a gift that the gods bestow but on the chosen few. I am, Sir, yours, &c.,

Canterbury, August 9th, 1882.

J. BRADNELL GILL, M.D.

Mr. A. Bywater.—The case has a certain amount of interest, but the circumstance mentioned is not unusual in the canidæ.

### HIGH TEMPERATURE IN PUERPERAL FEVER.

To the Editor of THE LANCET.

SIR,—Perhaps the following notes may be interesting to some of your readers:—

Mrs. A.—, a strong and healthy lady, aged twenty-eight, was delivered on April 13th of her second child. She had a comparatively easy labour, of about three hours' duration; a knee presentation. Her condition seemed in every way satisfactory until the 15th, when at 6 o'clock P.M. she had a severe rigor. On the same evening, at 10.30, I found her in a state of high fever, complaining of headache and pain in the right iliac region. The pulse was full, 134; temperature 105.4°. The tongue was coated with a white fur, and the bowels had acted freely during the forenoon, after a dose of castor oil. Lochia normal.—16th, 10.30 A.M.: Patient feels better; has passed a fair night; pain less. Lochia diminished, but offensive to the smell. Pulse 125; temperature 104.9 P.M.: Patient expresses herself better; pain entirely ceased; also the lochia. Pulse 122; temperature 103.5°.—17th, 10.30 A.M.: Has had a good night; complains of nothing except her thirst. Pulse 118; temperature 103.1°. 9.30 P.M.: Much the same; slight attack of diarrhoea. Pulse 130; temperature 105.2°.—18th, 10 A.M.: Has had another fair night; bowels stayed. Pulse 133; temperature 105°. 10 P.M.: No change since morning visit. Pulse 130; temperature 106.1°.—19th, 9.30 A.M.: Patient in same condition. Pulse 130; temperature 105°. 10 P.M.: No change. Pulse 133; temperature 105.4°.—20th, 9.30 A.M.: Has passed a restless night; bowels relaxed again; complains greatly of thirst. Pulse 133; temperature 106.1°. 8.30 P.M.: Patient is delirious for the first time; bowels still relaxed. Pulse 148; temperature 109.8°. Died at 1.20 A.M. on the 21st.

The pain in the right iliac region ceased during the afternoon of the 18th, and there was not any swelling of the abdomen up to the time of her death. The remedies I used in this case consisted of fomentations in the early stage, with injections of Condy's fluid; also acetic, sulpho-carbolic of soda, quinine, and the wet sheet. I may add that this case had its origin in scarlet fever poison, as I found out unfortunately too late.

I am, Sir, yours faithfully,

Keighley, August 7th, 1882.

F. HARRISON TETLEY.

## SUICIDE IN PHILADELPHIA.

In a paper read by Dr. J. G. Lee at the recent session of the American Medical Association the author stated that his experience was opposed to that of European observers in respect of the frequency of suicide amongst the married of both sexes. In 636 cases which were made the subject of judicial inquiry in the city and county of Philadelphia, 444 were of married persons, 138 single, and in 54 cases the question of marriage was not ascertained. Of the 444 married persons, 370 were males, 74 females. Of the 138 unmarried, 109 were males, 29 females. Of the 54 whose condition was unknown, 47 were males and 7 females.

A. B. E.—The work may doubtless be obtained of Sampson Low and Co., Fleet-street.

## "THE ABORTIVE TREATMENT OF GONORRHOEA."

To the Editor of THE LANCET.

SIR,—Mr. Watson Cheyne's interesting paper on the above subject in the current number of THE LANCET has induced me to send you a few practical remarks on the treatment of a malady which, through my former connexion with the Contagious Diseases Act at Woolwich, I have had special opportunities of observing. I arrived at my conviction as to the best mode of treating it on the following data, which I have placed in the order of their importance. Firstly, two diseased surfaces in constant and close apposition with each other are unfavourably placed for recovery, therefore I separate the walls of the inflamed urethra by ordering injections of hot water to be retained for twenty minutes or longer when practicable; but as the fingers would become cramped from holding the extremity of the penis for that purpose, Messrs. Krohne and Seemann have made me a simple spring forceps that conveniently takes their place, and, moreover, thus liberates the hands, which may be employed to hold a book, &c., to while away the tedium. Secondly, the gonorrhoeal discharge being capable of producing the disease when applied to a mucous surface, it is not unreasonable to suppose that its retention within the urethra must very largely perpetuate and exaggerate the inflammatory condition and stage; therefore the injections already recommended, when frequently used, will have a salutary effect in this respect also. Thirdly, it being well known that hot fomentations and poultices are soothing and emollient in all acute inflammations, it follows that hot injections within the urethra and hot baths and the application of fannels wrung out of hot water to the parts externally must be very beneficial. And, lastly, certain drugs that have a styptic effect upon the genito-urinary mucous tract are plainly indicated. But experience proves that they can only be administered with benefit after the more acute symptoms have subsided. I therefore give the liq. copalivæ comp. of Messrs. Hewlett and Sons when that stage has been reached, which is generally the case within a few days under the treatment indicated, and at the same time add three drops of liq. plumbi to each ounce of the injection, which must now be made with distilled water, and used less warm, or altogether cold. In some cases weak injections of nitrate of silver or chloride of zinc may now be of great use. I need scarcely add that the regimen, alimentary and medicinal, must be strictly non-inflammatory in the acute stage. Will you permit me to say, in conclusion, that I think the *modus operandi* of Mr. Cheyne's treatment and mine is very much the same—viz., separation of the walls of the urethra, dilution of the discharge, and lubrication of the inflamed surfaces with the cocoa-butter bougies. His objection to injections that their effects "are only momentary" cannot apply to the manner in which I recommend them.

I am, Sir, yours faithfully,

BERESFORD RYLEY, M.D.,  
Formerly Assistant Visiting Surgeon at Woolwich,  
under the Contagious Diseases Act.

Finsbury-square, E.C., August 5th, 1882.

Mr. Haggart.—The announcement appeared in our issue of last week, page 208.

Dr. Angus Mackintosh.—Thanks.

## A MEDICAL SICK FUND.

To the Editor of THE LANCET.

SIR,—I have long wished to make a suggestion to my professional brethren (and can only do so through the medium of THE LANCET) that there should be for us all a sick fund or club by which a man, when he is totally disabled, shall receive sufficient sick pay to keep him going and to pay a locum tenens. Suppose each medical man were to subscribe £2 2s. a year, and in case of illness from disease or accident he would during his incapacity from attending to his professional duties receive, say, £10 a week. I would leave the management of rules, &c., to a committee appointed for the purpose, and I only wish to place the skeleton of the idea before the profession, and leave it to more experienced heads to put it into working order. I am sure that many a man is working hard out-doors when he ought to be in bed, and thus perhaps sowing the seeds of some disease which, with proper rest, might be avoided. These cases are so numerous that it is obvious some remedy should be sought for them. I have been called up at night, and had to go six miles in the rain and snow, with jaundice, ulcerated throat, and a temperature of 102°, thereby lengthening my convalescence by quite a fortnight. How many have fared worse still? But they cannot afford to pay a locum tenens £3 3s. a week, and so they slave on in misery. Of course if such a club were started each sick member should get a certificate signed by two medical men, if possible, both when he goes "on the box" and when he goes off.—I am, Sir, faithfully yours,  
Bristol, August 8th, 1882.

A. H. BOYS, L.R.C.P. Ed.

## DANGERS OF TOY PISTOLS.

THE *Boston Medical and Surgical Journal* of July 27th reports six cases of tetanus following the infliction of wounds by toy pistols. Five of them occurred in the service of Dr. Ingalls, of the Boston City Hospital, all of them fatal. The sixth is recorded by Dr. Millet, of Rockland, and also terminated fatally. The imperfect construction of the cheap instrument is supposed to determine the perilous nature of a wound inflicted by it.

Mr. C. Winkworth should consult our advertising columns.

Mr. Ellis.—Thanks.

## DISINFECTION.

To the Editor of THE LANCET.

SIR,—Can you refer me to experiments proving at what temperature the vitality of the infective matter of scarlatina and small-pox is destroyed, and what is the best known portable disinfecting apparatus for taking into country districts to disinfect by heat?

I am, Sir, yours faithfully,

Notte, August 5th, 1882.

CHARLES WILLS.

\* \* There are no experiments of sufficient accuracy to decide the exact temperature at which any of the specific poisons are destroyed. Hence it is desirable to submit articles to the highest possible temperature short of damaging them, and the experiments made by Dr. Ransome, F.R.S., of Nottingham, have gone to show that in a stove so constructed as to ensure in all parts of its structure, and also in all parts of the articles contained in it, a uniform temperature of some 245° to 255° Fahr., complete success is in every respect attained. This uniformity of temperature cannot, we believe, be obtained in any portable stove, and since with a properly constructed cart infected articles can be easily conveyed to a stationary stove, we do not regard the absence of a thoroughly efficient portable stove as of any consequence. The best hot-air disinfecting stove is unquestionably that designed by Dr. Ransome, and manufactured by Messrs. Goddard and Massey, of Nottingham. The best steam disinfectant is Messrs. Washington Lyons' apparatus.—Ed. L.

Mr. G. Abbott.—Thanks. The point has not been overlooked.

## SCOTCH MEDICAL SCHOOLS.

To the Editor of THE LANCET.

SIR,—As I received the greater part of my medical education at the University of Glasgow, I take great interest in the letters of your correspondents. There is, however, a statement in "Scottish Notes" in this week's LANCET which should scarcely be allowed to pass without notice. The writer wishes your readers to believe that English students flock to Scotland because of the "good teaching." It may be on this account to a great extent, but not altogether, as no doubt the fees for lectures and hospital practice and the expenses of living induce many to study in Scotland who would otherwise go to London.

In my student days, now more than twenty-five years ago, the fees payable at the University of Glasgow were three guineas for a first course of lectures, and only two guineas at the Andersonian Institution, where most of the English students attended. Hospital practice at the Royal Infirmary to qualify for the College of Surgeons and Apothecaries' Hall could be attended for ten guineas, including clinical lectures.

Contrast these fees with those payable in London, which amounted to £24 at St. Bartholomew's. Also the diploma of the College of Surgeons, Edinburgh, or of the Glasgow Faculty could be obtained for considerably less than that of the London College of Surgeons.

Anyone desiring to know more of Scotch students and Scottish universities should read the very interesting article, "College Life at Glasgow," by Dr. Boyd, a Presbyterian minister at St. Andrews, and Mr. Gladstone's rectorial address, delivered at Glasgow in December, 1879.

August 5th, 1882.

I remain, Sir, yours truly,

ALPHA.

Dr. Ward Cousins.—The notice appeared in our last issue, p. 188.

## ECZEMA AND VACCINATION.

To the Editor of THE LANCET.

SIR,—A sad instance of the evil consequences of postponed vaccination has just come under my notice in the person of a child suffering from eczema. The cutaneous malady commenced about the age of three months, and owing to its persistent character it was agreed by the doctor in charge that the vaccination should "stand over." When two years of age this child was stricken down with confluent small-pox, scarcely escaping with its life, and now presenting an amount of facial scarring terrible to witness. Although many other persons dwelling in the same street were included in the epidemic, it is important to notice that the five other members of the family who remained in the house during his illness, and who had been successfully vaccinated, were unaffected throughout. It has been my frequent experience in hospital practice to see patients suffering skin diseases allowed to "stand over" from the protective influence of early vaccination, and therefore running equal risk.

The brief narration of the above case may perchance prove a timely warning to those of my professional brethren who hesitate to vaccinate so long as eczema is present.

I remain, Sir, yours faithfully,

Finsbury-circus, E.C., Aug. 1882.

J. HERBERT STOWERS, M.D.

## THE GALLWEY FUND.

THE appeal made some months ago on behalf of the widow and children of the late Dr. J. H. Gallwey, who died suddenly on Nov. 27th, 1881, leaving them in destitute circumstances, has, we understand, resulted in the collection of £400. Mrs. Gallwey has also obtained an award of £20 for this year from the British Medical Benevolent Fund.

**CORRIGENDUM.**—In THE LANCET, Dec. 3rd, 1881, page 969, we referred to the use of carbolic acid in the cure of hydrocele as practised by Dr. R. J. "Lewis;" it should have been Dr. R. J. Lewis.

**COMMUNICATIONS, LETTERS, &c.,** have been received from—Sir W. Smart, London; Dr. Plowright, King's Lynn; Mr. Tetley, Keighley; Dr. Long Fox; Mr. Vincent Richards, Gualundo; Dr. W. R. Smith, Cheltenham; Dr. de G. Griffith, London; Dr. Campbell Black, Glasgow; Dr. Ward Cousins; Mr. Sydney, Hounslow; Messrs. Rogers, Rock, and Co., Droitwich; Mr. Morley, Birmingham; Dr. Shuttleworth; M. Decroix, Paris; Mr. W. Berry, Wigan; Dr. H. Stowers, London; Dr. Scriven, London; Mr. P. E. Hill, Crickhowell; Messrs. Nicholls and Co.; Mr. Brennan, Dublin; Dr. Duffield; Mr. Shirley Murphy, London; Mr. R. Ellis, Newcastle; Mr. J. L. Gibson, Edinburgh; Dr. Pearson, Maryport; Dr. Ryley, London; Dr. Morrison, London; Dr. Meredith; Mr. Sutcliffe, Over Darwen; Dr. Lesser, Leipzig; Mr. Carpenter, London; Mr. Cross, Petersfield; Dr. Fulton, Toronto; Mr. Stephens, Winchcomb; Mr. Whitmore, Dursley; Mr. Housley, Leicester; Mr. Barnes, Axminster; Mr. Mortimer, London; Mr. Butterfield, Northampton; Mr. Julian, Penzance; Mr. Kershaw, Normanton; Mr. Griffiths, Penygros; Mr. Brookhouse; Mr. Wills, Mansfield; Dr. Fisher, London; Dr. Thin, London; Mr. Mark Judge, London; Mr. Wyllie, Cloughton; Mr. Skirving, Edinburgh; Mr. Boys, Pill; Dr. Angus Mackintosh; Dr. Marshall, Nottingham; Mr. Cullimore, London; Dr. Fraser, Salford; Dr. Campbell, Newcastle; Mr. Watson Cheyne, London; A. R.; Alpha; Endymion; T. N. O.; Enquiries; L.R.C.P., Stoke Newington; Medicus, Clapham; A. B., Colchester; R.; A. B. B.; &c., &c.

ON

## PAIN AT THE HEART AND PALPITATION.

*Delivered in King's College Hospital,*

By I. BURNEY YEO, M.D., F.R.C.P.,

PHYSICIAN TO THE HOSPITAL.

### LECTURE I.—(Concluded.)

IN the next case we had repeated opportunities of exploring the sensibility of the præ-aortic, the præcordial, and the lower cervical regions, as this patient was in the hospital for some weeks, and he was examined several times at suitable intervals, both by Mr. Silk, the house-physician, and myself, and the painful spots were carefully marked. He also derived much benefit from local as well as general treatment.

George K—, aged twenty-two, was admitted into King's College Hospital complaining of pain and weight in the cardiac region, the pain shooting down the left arm. The attacks of pain were very severe at times, and prevented him from sleeping; the pain was also much aggravated by exertion. He suffered also from dyspnoea. Had never had acute rheumatism or other acute disease. His father died

FIG. 2.

of heart disease. Twelve months ago he used to suffer from momentary attacks of loss of consciousness, which were followed by some dyspnoea, and he was unable to work for two or three days after the attacks. His countenance was pale and anxious, and he looked much older than his age. On examination of the chest, the area of cardiac dulness was found to be much increased; the apex-beat was diffused, and felt in the seventh interspace an inch and a half outside the nipple line. A loud double murmur was heard at the base of the heart, most intense in the aortic area, but conducted in all directions over the cardiac region and into the large vessels on both sides of the neck. There was notable pulsation of the carotids and brachials. The radial pulse was collapsing, 84; the arterial coats thickened and uneven. The sphygmograph gave the characteristic tracing of aortic regurgitation.

As "pain at the heart" was a very marked feature in this case, a careful examination was made, with a view of discovering any specially painful spots, and the following points were found extremely tender on pressure with the point of the finger. Two points close together over the cardiac apex, which beat in a diffused manner in the seventh interspace; a point in the third left interspace, close to the sternum; a similar point in the first left interspace; a similar point at the sternal end of the second right interspace, and two points over the course of the vagus in the neck, just in front of the anterior border of the sterno-mastoid, one immediately above the supra-sternal notch, the other about an inch and a half higher up.

The treatment of this patient consisted of rest in bed and a diet composed largely of milk; small doses of digitalis with citrate of iron, sometimes with ether and ammonia; No. 3077.

occasional hypodermic injections of morphia when the cardiac pain was very severe; and small flying blisters over the base of the heart.

He remained in the hospital seven weeks, and left greatly improved in health, the pain and dyspnoea both greatly relieved. The situations of the painful spots are indicated in this diagram. (Fig. 2.) We may believe that in this case there not only existed neuritis of some of the nerves of the cardiac plexus, but also some chronic myocarditis, and more or less degeneration of the cardiac muscle. Hence the pain at the apex, where the degeneration is usually most advanced, while the number of painful spots over the cardiac base and along the course of the vagus pointed to a somewhat diffused neuritis of the cardiac nerves.

Another case somewhat similar to the preceding is in one of my beds in the hospital at the present time. In this case, however, we have had occasional paroxysmal attacks of cardiac pain, bringing it more nearly into the category of cases of angina pectoris, and these paroxysmal attacks have been relieved by the administration of nitrite of amyl. In this case also there has been marked tenderness on pressure over the course of the vagus in the neck. The following is a brief abstract of the case from the notes of my clinical clerk, Mr. C. G. Hodgson.

W. L—, aged twenty-nine, has twice had acute rheumatism, and is subject occasionally to epileptic attacks. Complained on admission of having suffered much from pain in the cardiac region for the past two months. The pain, beginning in the region of the heart, spreads over the whole of the left side of the chest, and is associated with much dyspnoea. The physical signs pointed to considerable cardiac hypertrophy, and to the existence of both obstructive and regurgitant aortic valve disease. Very marked pulsation of vessels both in the neck and arms. This patient was at first much relieved by counter-irritation, in the form of flying blisters over the cardiac base, together with small doses of morphia in ether mixtures. Subsequently he was attacked at night with paroxysms of pain and dyspnoea of an anginal character, and these were completely relieved by inhalation of nitrite of amyl. In this case, as in that of Geo. K—, there were very distinct tender points on pressure over the course of the vagus in the neck, as well as in the first and second left intercostal spaces close to the sternum.

The next case is one of considerable interest, not so much because of the existence of cardiac pain, although it is on that account that I now call your attention to it, but because of the co-existence of chronic inflammation and induration, and contraction of the left lung, with repeated attacks of hæmoptysis as a consequence of chronic mitral valve disease of eleven years' standing, itself the consequence of repeated attacks of acute rheumatism. The interesting aspects of this case from the point of view of pulmonary pathology I shall hope to have another opportunity of presenting to you, but now I introduce it for the purpose of illustrating the subject of cardiac pain, and this time it is associated not with aortic, but with mitral disease.

M. H—, a female, aged thirty-two years, has been under my observation for more than four years both as an out-patient at the Brompton Hospital and as an in-patient in this hospital. For the present I must confine myself to the consideration of her complaint of "pain at the heart," for which she was admitted into the hospital in the spring of last year. At that time she was suffering from severe pain in the cardiac region, extending into the back between the shoulders. The heart, which presents evidences of hypertrophy, is much uncovered by retraction of the left lung. The apex-beat is diffused and heaving, and attended with a palpable thrill. There is also visible and palpable pulsation in the second and third left interspaces; loud murmurs, varying occasionally in rhythm, are heard widely over the cardiac area; sometimes both a presystolic and a systolic murmur can be heard; at other times a loud systolic murmur only can be distinctly recognised, loudest over the apex. On exploring the following painful points, as shown in the diagram (Fig. 3). One in the second left interspace, where pulsation the cardiac sensibility we made out clearly the existence of is strongly marked; three points close together in the fourth interspace, and two points close together over the rounded apex in the sixth interspace. In this case also there exist no doubt tendencies to chronic changes in the cardiac muscle of an inflammatory and degenerative nature, conferring upon it a morbid sensibility, which becomes evident on exploratory pressure over the superjacent parts of the chest wall. By rest in bed, small doses of digitalis and iron,

G

the local use of the belladonna and chloroform liniments combined, but chiefly through the influence of counter-irritation in the form of small flying blisters, the pain was relieved, the cardiac action regulated, and her health generally improved, and she left the hospital, after a stay of six weeks, in very fair health. As you might suppose, she has again come under observation, and her case will

FIG. 3.

again afford us an opportunity for clinical study, but next time from a different point of view.

The next case is one in which the cardiac disturbance was purely functional, and although this patient had suffered from palpitation and pain at the heart for a long period, after a few weeks of appropriate treatment she was completely relieved.

L. D—, aged twenty-five, a housemaid, accustomed to carry heavy trays upstairs, came under my care at the Brompton Hospital recently complaining of "pains at the heart darting through the chest," and of "palpitation." She could not move without distressing palpitation, from which she had suffered for many years. This had been aggravated during the preceding six months and accompanied with dyspnoea and throbbing in the heart. The pain, referred to the centre of the chest, was worse after taking food, and also on attempting to go upstairs, and she often had to stop and sit down on the stairs. She also suffered from dysmenorrhoea, from flatulence and

FIG. 4.

constipation. She drinks a quantity of tea, often three times a day. Her cheeks were slightly flushed, but her lips and gums were pale and bloodless. On examination of the chest the heart's impulse was seen to be greatly exaggerated, and the large vessels at the root of the neck pulsated strongly. Pulse 120. No abnormal cardiac or vascular murmur could anywhere be detected. On exploring the cardiac sensibility with the tip of the finger the following painful points could be made out distinctly as in the diagram (Fig. 4)—viz., a point at the sternal end of the first, second, and third left interspaces, and another immediately over the apex-beat. She was ordered to abstain altogether from tea, and she was given three minims of tincture of digitalis in an ounce of the calumba and iron mixture of the Brompton Pharmacopoeia three times a day, and a pill of aloes and nux vomica daily after dinner. A week after the commencement of this treatment she reported herself as much freer from pain and palpitation, and as feeling stronger. The pulse was reduced

from 120 to 108. After a second week the pulse was reduced to 84, and she felt better "in every way." The painful spots were less sensitive, and that over the apex had disappeared. At the end of a month she was quite well and the painful points had entirely gone. Now this appeared to be a well-defined and instructive case of disturbed cardiac innervation, and a painful state of the cardiac muscle induced by the abuse of tea, and by the defective blood formation due to the dyspepsia also set up by this agent, while the morbid cardiac condition was no doubt augmented by the severe muscular exertion she was called upon to perform in connexion with her occupation. The rapid and complete relief of the long-standing cardiac pain and palpitation was as instructive as it was gratifying.

The following case is, in some respects, parallel to the one I have just cited, but it has this special interest that the attacks of pain were sudden and paroxysmal, approximating it to true "angina," and bringing into relief the true affinity between these minor attacks of cardiac pain and the graver cases of angina pectoris.

Elizabeth E—, aged twenty-one years, also a housemaid, had suffered from severe pain in the cardiac region, first brought on by carrying heavy trays upstairs. The pain came on suddenly two or three times a day, and extended down the left arm, which went "stone cold," to use her own expression. She also complained of much pain in the left vertebro-scapular region, and there was some tenderness on pressure over the intercostal spaces in this region. She suffered also from dyspnoea, and was losing flesh. There was a flush on the cheeks, and she complained of headache. There was no abnormal cardiac or vascular murmur. Pulse 100, feeble, and of low tension. On testing the cardiac sensibility marked tenderness was found in the third left interspace, close to the sternum, the tenderness extending outwards for about three-quarters of an inch. There could be no doubt about the distinct localisation of extreme tenderness in this spot. There was also a tender point, but much less sensitive, over the apex. She was at first ordered the calumba and iron mixture of the Brompton Pharmacopoeia three times a day, and the local application of the mixed chloroform and belladonna liniments. This treatment, persevered in for four weeks, gave but little relief. The cardiac pain and tenderness remained, and there was a certain amount of general nervous disturbance. She was ordered five grains of bromide of potassium three times a day, with the calumba and iron mixture—a form I have found exceedingly useful when there is a combination of anæmia with neurotic symptoms—and a small flying blister, about the size of a florin, to be applied for two hours at a time over contiguous spots at and near the sternal end of the third intercostal space. After a fortnight of this treatment she was much relieved, and at the end of six weeks she reported herself as better in every respect. She scarcely ever had pain in the chest or arm, and the tender points in the præcordial region had disappeared.

It must be remembered that these cases have been selected, out of a vast number of other patients complaining of a variety of chest affections, because of the special features they presented. In this last case we no doubt had a form of cardiac neuralgia, probably induced by cardiac strain or over-fatigue, and having many points in common with angina pectoris. It is remarkable how in this, and many other like cases, the cardiac tenderness seems to be specially localised about the sternal end of the second or third intercostal space, and how completely the symptoms were relieved by counter-irritation over this spot.

The next case, to which I wish to call your attention, bore a strong analogy to the two preceding ones, and is very instructive as bridging over the not very wide gap, I imagine, which separates these cases from true angina pectoris; and the fatal termination of this case, after only a few months' illness, shows how grave was its character. This patient, a stout, healthy-looking, single woman, twenty-nine years of age, was also in the habit of carrying heavy trays upstairs in her occupation as a waitress. Her family history was good, and, except two or three attacks of bronchial catarrh, her previous health had been good. She first came under my notice in January, 1881, as an out-patient in this hospital, complaining of "pain at the heart." She stated that she was perfectly well eight months ago, but about that time began to suffer from sharp attacks of pain in the cardiac region, shooting down the left arm, coming on suddenly on any exertion, such as carrying heavy trays upstairs, and it was after an exertion of this kind that the pain first came

on. She describes the attacks as of a "stiffing" character, as she cannot "move the chest to breathe," and the pain, which, not very severe at first, has gradually increased in severity, shoots into the left shoulder and down the left arm, and leaves the arm "cold and numb." You will remember that in the preceding case the patient said her left arm went "stone cold."

Before examining the patient's chest I pointed out that her attacks resembled those of angina pectoris, and that we might or might not discover the existence of some organic disease of the heart. After the most careful examination of the heart, in which one of my colleagues joined, no distinct cardiac murmur could be made out, but I called attention to an alteration in the sounds over the aortic area, which I ventured to predict would become altered into murmurs. There was a slight roughening and prolongation of the first sound, and a marked accentuation of the second sound. Moreover, there appeared to me to be a loss of resonance on the right side of the sternum over a very limited area corresponding with the second and third cartilages and second interspace, which made me think of dilatation of the aorta or of the possible development in that situation of an aneurismal sac. A fortnight later the roughened first sound had become a distinct systolic murmur, and the accentuated second sound ended in a diastolic bruit, which was conducted downwards to the left of the mid-sternal region. As the paroxysmal attacks of pain had gradually increased in severity and in frequency, coming on now on the least exertion, and sometimes even when in bed, she was induced to come into the hospital. She had many attacks while in the hospital, but they were by no means of that agonising character sometimes seen. For the first three weeks she improved; the attacks were only momentary, and occurred with a good deal of irregularity; sometimes she would have two in a day; sometimes she would go a week without an attack. In the intervals she felt quite well. The attacks would often occur when she began to get up in the morning or after walking about a little in the ward. We tried iodide of potassium without benefit; flying blisters over the cardiac base relieved her somewhat. In the beginning of March her attacks became more frequent, and we gave her nitrite of amyl, but without any good result; then we tried nitro-glycerine in gradually increasing doses. We began with half a minim of the one per cent. solution, and increased it to three minims three times a day. Under this treatment she mended somewhat, and, feeling better at the end of March, she left the hospital by her own wish to visit some friends, and promised to return in a week, but the very day she was to have returned to the hospital she died suddenly, after bringing up a quantity of blood. Unfortunately we could not get a post-mortem examination. I regret also that I had not then adopted the mode of exploring the cardiac sensibility, which I have applied in all the other cases I have brought before you, as well as in many others, into the particulars of which it would take up too much of our time to enter.

These last three cases, varying so greatly in severity and seriousness, appear to me to have many points in common. Their causal relationship is obvious. All three patients were young women in fairly good health, with no antecedents leading to cardiac disease, save that they were all of them engaged in the same kind of occupation, and they all three complained of the effects of carrying heavy trays upstairs. In the first and slightest of the cases the cardiac disturbance was undoubtedly aggravated by the abuse of tea. In all three, but especially in the last two, the symptoms complained of bore a striking likeness to one another. In neither of them, when first seen, was there any definite cardiac murmur. May we not trace the varying effects of cardiac or vascular strain in each of them? In violent and sustained muscular efforts there is increased action of the cardiac muscle on the one hand, and increased resistance at the periphery from muscular compression of the arterioles and capillaries on the other. If the cardiac muscle is weak and anæmic, as a part of a general anæmia, then the ventricular wall may yield and become dilated, and we may get palpitation and pain associated with fatigue and mal-nutrition of the cardiac muscle, as was no doubt the case with the first of these three, and probably to some extent with the second. But supposing the tone of the cardiac muscle to be good, and its contractions sustained and vigorous, then we should expect the strain to be felt especially in the first part of the aorta, for it has to endure a twofold distending influence: it has to bear the increased impetus of the ventricular outflow, increased both

in force and frequency, and the increased resistance in the peripheral vessels. Under these influences it may become the seat of chronic inflammatory changes (as we know it constantly does), which may extend to and involve the nerves of the cardiac plexus in relation with its walls, or a particular weak portion of its wall may yield and dilate and become the seat of an aneurismal sac, as was most likely the case in the third patient.

The causation, the localisation, the pathological relations, and the treatment of cardiac pain in the various cases which come before us in which this symptom occupies a prominent place, are well deserving of your careful and continued investigation. It is for this reason I have brought the subject under your notice in some detail, and have described to you a method of exploring the sensibility of the cardiac and aortic regions, which promises to be as instructive as it is simple.

## CARCINOMA OF THE LEFT LUNG AND PLEURA.

WITH REMARKS.

By HENRY DAVY, M.B. LOND., M.R.C.P.,

PHYSICIAN TO THE DEVON AND EXETER HOSPITAL  
AND TO THE EXETER DISPENSARY.

I AM indebted to Mr. W. Brewster, then clinical assistant to the hospital, for many of these notes.

Philip S—, aged forty-three; admitted July 21st, 1881. The patient has a good family history. He has worked in a sawpit, and has enjoyed good health up to the date of his present illness. Eight months ago he began to suffer from a troublesome cough, and after a time he became a patient under one of my colleagues in the Exeter Dispensary, by whom he was treated for phthisis. Subsequently he came under my own care, and, finding dulness and bronchial breathing at the left apex, I also considered it a case of phthisis for two or three weeks. Finding that his symptoms were hardly explicable on this view, I examined him more carefully, and persuaded him to enter the hospital under my care.

*On admission.*—The patient is a tall thin man, with an unhealthy-looking and emaciated appearance. His complexion is sallow, and there are venous stigmata about the cheek and nose. Lately he has lost flesh very rapidly, and he now has no appetite for any kind of food. There has been no hæmoptysis, but he has a very severe cough, especially at night, and he expectorates a good deal of phlegm. He complains of great pain in the left side, which, he says, sometimes causes him a "perfect agony." He cannot sleep at night, being kept awake partly by pain and partly by the cough. His bowels are constipated, but his tongue is clean and moist. His pulse is regular, but weak, and his temperature is about normal.

On examination, the heart, liver, and right side of the chest appear quite normal; urine contains no albumen, specific gravity 1020. The left side of the chest hardly moves at all in respiration. It is almost universally dull both back and front, and there is a great feeling of resistance to the percussing fingers. Tactile vibration is entirely lost, but no ægophonic sounds can anywhere be detected. Scarcely any air can be heard entering the lung either behind or in the axillary line, but in front, from the clavicle to the nipple-line, there is bronchial breathing. The intercostal spaces do not bulge—in fact, they appear flatter than on the right side, and by careful measurement it is found that the left side is rather more than an inch smaller than the right. Vocal resonance is everywhere diminished, and there is no bronchophony or pectoriloquy at any part of the chest. The chest was punctured by an aspirator in several places, but no fluid was found. The aspirating needle appeared to enter solid matter even when it was passed into the chest for a couple of inches.

From this date (July 21st) patient steadily got worse. He was very restless at night, and the pain in the left side was very severe, in spite of all the usual treatment for this symptom. He could not sleep at night, and he lost both appetite and weight. His heart began to fail, and on Aug. 11th the liver became enlarged and some ascites was

detected. In deference to expressed opinions that there might be fluid in the chest, an aspirating needle was more than once used, but always with the result that no fluid was found. The ascites steadily increased, the measurement round the umbilicus being about one inch larger every day, while œdema of both legs and scrotum was also developed. His morning and evening temperature were about normal, but his pulse was often very weak and rapid. I dictated the following note:

Aug. 18th.—Patient is very restless, and is obliged to sit propped up in bed. His breathing is very quick and shallow, and he complains much of pain in his left side. There is œdema of the legs, more especially the left, and the scrotum and prepuce are also œdematous. Liver dullness commences at the fifth rib, and extends almost down to the umbilicus. The enlargement is evidently due to congestion, is smooth and uniform, the liver edge being easily felt just above the umbilicus. As he sits up in bed the dullness due to the ascites commences three fingers' breadth below the umbilicus, while there is dullness in both flanks continuous with the liver dullness above. A distinct thrill can be felt from side to side through the fluid. Lungs: Behind on the right side the air does not enter well at the extreme base, and there is a slight amount of râles, probably due to œdema of the lung. The rest of the lung, both back and front, is normally resonant, and the breath sounds are puerile over it. At the extreme base of the left lung the percussion note is altered by intestines or stomach, but everywhere else the percussion note is absolutely dull. Very deep inspiration is accompanied at the extreme base by a coarse gurgling râle, higher up by a good many coarse râles, but over the greater part of this lung no air can be heard entering at all. Heart sounds appear normal, and the apex beat is hardly if at all displaced. From this date the patient became weaker and his breathing more and more shallow, and on Aug. 31st he died. Unfortunately I could not be present at the post-mortem, which was made by Dr. Blomfield, the house-surgeon. The lung was, however, kept for my inspection. I dissected out the root of the lung, and made sections of the tumour, whilst some very beautiful sections were also made for me by Mr. W. Brewster and by Dr. Heneage Gibbes, curator of the Anatomical Museum, King's College.

*Necropsy.*—Chest: On opening the thorax a considerable quantity of straw-coloured fluid escaped from both pleural cavities. On the right side the pleura appeared to be healthy, no thickening being found on any part either of the costal or visceral layer. The lung too was crepitant throughout, and, with the exception of some œdema, appeared quite normal; its weight was 1½ lb. On the left side the lung was bound back in the vertebral groove, and was covered all over by a thick layer of a yellowish-white colour, which fixed it so tightly to the costal surface that it was removed with great difficulty. The whole of the costal pleura from base to apex was very greatly thickened, and was of the same yellowish-white colour as the pleura over the lung. In some parts the thickness of the costal pleura was two inches, and in no place was it less than half an inch. When cut into it had a hard, fibrous feel. The space between this thickened pleura and the lung was filled with straw-coloured serum. On removing the lung and cutting into it, it was found to be covered all over with a thickened pleura, from all parts of which the lung tissue itself was invaded by bands of a similar nature to the thickened pleura. In parts the lung tissue was entirely destroyed, this being especially true at the apex, base, and in the neighbourhood of the root of the lung. In these situations the lung was completely solidified and airless, almost white, and cut with a fibrous feel. The parts contiguous to these were solidified and airless, but the black mottling of lung tissue could be recognised; while in some parts the lung was imperfectly crepitant. On dissecting out the root of the lung it was evident that the new growth was oldest and most advanced in this situation. Around the principal bronchus it was of considerable thickness, a large mass of it almost obliterating the bronchus embedding the bronchial glands, and spreading for some distance around the divisions of the bronchi into the lungs. The bronchial glands were enlarged, but most of them could be recognised in the midst of the growth, by which they were often comparatively little invaded. Some, however, were much invaded by the growth, and one which contained a small mass of calcareous matter had very little glandular structure recognisable. In no part of the lung were any dilated bronchi or cavities to be found. Weight of lung plus mass of new growth removed with it, 3lb. 14oz. Heart and pericardium: The pericardium con-

tained some straw-coloured fluid, but no growth. The heart (left side) was normal; the right side was dilated, and the muscular walls slightly thickened. The abdomen contained a large quantity of inoffensive dirty-yellow-coloured fluid. The intestines were normal. The liver was large, smooth, and congested; no new growth anywhere in it. The kidneys were large, red, and congested, otherwise normal; the spleen was healthy; the abdominal glands were not enlarged. The head was not examined. Parts of the lung and pleura were hardened in Müller's fluid, and the microscopic examination of the sections made proved that the new growth consisted of a large amount of fibrous stroma, with masses of cells in the interstices; and there was no doubt that it was a carcinoma.

*Remarks.*—The rarity of cases similar to the one above related must be very great, for I have not been able to find any other recorded in which the physical signs were at all so well marked. It is true that cases are described in which large patches of dullness over thickened pleura were found; but in this instance the dullness was over the whole left side of the chest, and to a superficial examination resembled that found with a large pleuritic effusion. That it was not an ordinary case of pleurisy was, however, clear from the date of admission, the "diminished size of the chest" and the "flattening of the intercostal spaces" making the diagnosis of fluid improbable even before the use of the aspirator proved that fluid was not present. Nor was the condition of the patient like that of a man who had recovered from an acute pleurisy with a much thickened pleura. The absolute dullness of the whole side of the chest, the almost complete absence of breath sounds, the great pain patient suffered, together with his rapid emaciation and general appearance, proved that the primary cause of his illness was much more grave. In fact these symptoms, together with the others I have described, indicated to my mind that he was probably suffering from malignant disease of the lung and pleura; and during the course of his illness I saw no reason for considering any other diagnosis more compatible with his symptoms. The alternative diagnosis seemed to be that of "cirrhosis" or "fibroid phthisis" of the lung with thickening of the pleura, and there were several reasons for taking this view of the case. His dusty work in a sawpit was just that which might start the cirrhotic change, and this change limited (as it usually is) to one lung, with thickening of the pleura, have produced all the physical signs we have described; while the cause of his illness, with the failure of the heart, congestion of the liver, and ascites, was just that which ordinarily heralds the termination of advanced cases of cirrhosis of the lung. On the other hand, cirrhosis of the lung is very gradual in its onset, and very slow in its progress. The patient had enjoyed good health up to eight months previous to admission, and had performed laborious work up to that time without difficulty. It was very unlike cirrhosis of the lung to have increased so rapidly as in eight months to produce the physical signs I have described, especially as during this time the patient had been removed from all the causes by which the cirrhotic change in the lung would be kept up. These physical signs could only be produced by the most advanced cirrhosis of lung tissue, and that this should have begun almost suddenly and increased so rapidly was extremely unlikely. Nor would this pathological change have accounted for the pain I have described, and which I have said often amounted to great agony. A diagnosis of malignant disease of the left lung and pleura was therefore made and maintained from the first, and this diagnosis was completely verified by the post-mortem examination. The disease evidently commenced at the root of the lung, extending along both the visceral and costal layer of the pleura. Early in the case it apparently surrounded and almost obliterated the principal bronchus, and to this cause is probably due the collapse of the lung, which was found bound down with carcinomatous pleura in the vertebral groove. The extent to which the lung itself had been invaded was very great, so that very little crepitant tissue was left. Considering the probable seat of origin of the carcinoma at the root of the lung, I was surprised at the absolute freedom of the right lung and pleura from any trace of the growth, and it is also to be remarked that no secondary growths were discovered anywhere. As to treatment, sedatives of all kinds, with digitalis and stimulants for the failure of the heart, were freely used, but without any good effect whatever.

YELLOW FEVER has broken out at Brownsville, Texas, and is spreading with alarming rapidity.

## THE TREATMENT OF DYSENTERY.

BY J. B. SCRIVEN,  
LATE CIVIL SURGEON OF LAHORE.

THE following observations suggested themselves to me on perusal of Dr. Stephen Mackenzie's two interesting papers in THE LANCET of April 22nd and 29th, on the Treatment of Chronic Dysentery by Voluminous Injections of Nitrate of Silver. My remarks, however, refer principally, though not wholly, to the acute form of the disorder. I shall first say a few words on the point which forms the main subject of this paper—namely, the use of enemata in dysentery, and afterwards describe briefly the mode of treatment which I have found most successful.

1. *The Use of Enemata.*—The treatment of dysentery by large enemata, proposed by Dr. O'Beirne in 1822, was first extensively carried out by Surgeon-General E. Hare,<sup>1</sup> who at the time of the second Burmese war, 1852–53, was in medical charge of the 1st European Bengal Fusiliers, to which I was an assistant-surgeon. He had used this remedy for several years before he went to Burmah, and he wrote about it in the *Indian Annals of Medical Science* of April, 1854. He considered the large enema applicable both to acute and chronic dysentery; he recommended an injection of "warm water, without limit in quantity, till the patient complained of the distension, and the abdomen was visibly enlarged," and he sometimes medicated the water with sugar of lead, alum, or nitrate of silver. In fact, he maintained that large injections, combined with copious doses of quinine by the mouth, formed the true and rational treatment of a disease produced by malaria and characterised by ulcers of the large intestine. He administered his injections with a long flexible tube having one opening at the end, but none at the sides, and he passed it "above the sigmoid" flexure.

Following Mr. Hare's instructions, I also tried these large injections in some of the very severe cases I met with among the soldiers in Burmah, but I found them by no means so generally applicable as Mr. Hare believed. I, as well as many others, thought it undesirable to distend the abdomen as he recommended, and not always safe to pass the long tube through the sigmoid flexure; but I found, as Mr. Hare himself admitted, that often the enema could be effectually administered with the ordinary tube two or three inches long, or if not, with one of six or eight inches. But I found, on the other hand, that in the acute stage of dysentery the remedy in many instances was impossible, or was productive of so much distress that it could not be repeated. Nevertheless I know that it sometimes cured. An officer once applied to me immediately on the occurrence of the symptoms; I administered one large enema of warm water, I gave him four grains of opium immediately afterwards, and I heard no more of his dysentery. This is a parallel case to the single one recorded by Dr. Wood of Philadelphia,<sup>2</sup> in which acute dysentery was cured by three nitrate of silver enemata, the advantage being so far on the side of simple water.

In cases, however, in which ulceration has supervened upon the acute stage, the large enema is invaluable. In these I have steadily employed it through the whole course of my practice. In many instances I have simply used warm water, in others I have dissolved in it an astringent salt. The astringent I have invariably used of late has been alum, though a long time ago I tried nitrate of silver and acetate of lead. These two I abandoned, not because they failed or that I found them injurious, but because I thought they might some day produce symptoms of poisoning. This has not been lost sight of by Dr. Mackenzie, who mentions the suggestion of Dr. Wood (with instances from his own cases), that in the event of an enema of nitrate of silver being retained for twenty minutes, common salt should be injected as an antidote; but it appears to me that, if retention were to take place when the intestine was already well filled with fluid, it might be impossible to introduce a sufficient quantity of any antidote to neutralise the poison. However, I have found alum answer so well that I have had no reason to try anything else.

What is the best mode of administering the large enema? Mr. Hare proposed first that the patient should be laid on

his right side, with his pelvis a little raised, and his legs slightly flexed. This favours gravitation of the fluid into the transverse and ascending colon, and is, I think, an easier position to the patient than the lithotomy position adopted by Dr. Mackenzie and Dr. Wood. Secondly, Mr. Hare insisted on the fluid being slowly injected, and if there was any gripping the injecting process was to be stopped till this had ceased. Both of these precautions I consider essential to success. I never timed myself in giving the injection, but I think eighty ounces of fluid ought to occupy from ten to fifteen minutes. Nor have I been accustomed to test the temperature of the water with the thermometer, but my object has been to begin with it somewhat warmer than the body, perhaps 102° F., to allow of a little cooling during administration.

As to quantity, the large intestine will hold, in some cases, six imperial pints. As a rule, I order four pints to be prepared, and as much of this to be used as can be introduced without distress to the patient. If all these precautions are not observed, the remedy soon falls into disrepute.

An important, indeed essential, adjuvant to the large enema is the small enema. By the small enema I mean one of not more than three or four fluid drachms, containing thirty or forty minims of tincture of opium and a little mucilage. This, if given warm, is generally retained for some time, and often produces quietude of the bowels and sleep for several hours. The best instrument for it is a glass urethral syringe. If given cold, or if more than half an ounce be used, the small enema also fails in its purpose, and is soon expelled.

2. *The Treatment of Acute Dysentery.*—Dysentery most commonly begins in the night, and private patients very frequently apply to their medical attendant early in the morning. In a great number of cases diarrhoea has preceded the dysentery for a day or two, and the evacuations have often been of a light colour, indicating deficiency of bile. Be this as it may, a patient applying during the preliminary diarrhoea, or early in the morning after the supervention of dysenteric symptoms, is in many instances at once relieved by five grains of calomel, followed in three hours by from three to four drachms of castor oil or thirty grains of Gregory's powder. No opium should be given with any of these things. The effect often is an immediate cessation of the symptoms, there being no evacuation after the calomel, till the castor oil or rhubarb begins to act, this producing two or three liquid bilious motions without gripping or tenesmus. This treatment saves the strength, being less depressing than an immediate resort to ipecacuanha. I always forbid any kind of food or drink between the dose of calomel and the aperient, but allow some warm tea or chicken broth an hour or two after the latter. A day or two of rest with careful diet, and a little bark or quinine, with nitro-muriatic acid, in such a favourable case, will complete the cure. But suppose the calomel to have been given at 7 A.M., the castor oil at 10 A.M., and that, in spite of these, the dysenteric symptoms continue during the afternoon, with frequent purging and tenesmus, I then order eight leeches to the anus. These give so much relief that the patient can generally lie quiet for them to complete their work, and when they come off, a small enema is administered. Evening is now approaching, and about twelve hours after my first visit I order twenty grains of ipecacuanha with one grain of opium, in four pills, to be taken at once. The effect of this and the other remedies combined is commonly to produce a peaceable night, perhaps disturbed by one attack of vomiting, which I always advise the patient to avert, if possible, by lying perfectly quiet. If there is any dysenteric purging, the ipecacuanha and opium pills and the small enema are repeated after a second period of twelve hours, and similar instructions are given for each successive period of the same length. But if during any twelve hours' interval there is no dysenteric purging, the ipecacuanha is omitted, and a dose of castor oil (three or four drachms without opium) is taken, instead of any other medicine. It is well, for obvious reasons, to give this early in the day, so that I sometimes postpone it till the morning, giving an opiate overnight. One or two fecal evacuations are probably the result, and the disease is at an end. Diarrhoea may remain, which I have often been able to check with small doses of quinine, sulphuric acid, and landanum, or by some preparation of the bael<sup>3</sup> fruit. Tea with a small quantity of milk, or chicken

<sup>1</sup> See Dr. Joseph Ewart's paper on Tropical Diseases, *Indian Annals of Medical Science*, vol. viii., p. 369.

<sup>2</sup> *Philadelphia Medical Times*, Oct. 27th, 1877.

<sup>3</sup> See Sir Joseph Fayrer on Tropical Dysentery and Diarrhoea, p. 172.

broth, is the only food allowed during the active treatment, not more than a small teaspoonful every four hours; the nauseating effect of the ipecacuanha generally sufficiently limits the appetite. Such is the course of dysentery, in most cases, that apply for relief within the first three or four days. If the treatment be commenced later there is some danger of the disease running on to ulceration. When this has happened ipecacuanha, unless it be in one or two grain doses, is no longer useful. The time has come for the large enema and the bael fruit. The quinine mixture, with opium, just mentioned, also answers well in this stage, but I seldom give it if bael can be procured. Other drugs might also be named as substitutes for bael, and one of the best is tannic acid. The large enema may at first consist of simple water, but if improvement is not very marked, after two injections, I add to it alum, in the proportion of one grain to the ounce. Once a day is often enough for this remedy, as it is rather a tax upon the patient's strength. The evening is the best time, one or two grains of opium being given by the mouth, and the small enema by the rectum, as soon as the large one comes away. From this, good rest is obtained at night, and if another small enema be given in the early morning, there will perhaps be complete quietude of the bowels till the injection is repeated the following evening. If the evacuations (including the fluid of the large enema when passed away) be carefully examined every day, while they are being slowly poured from one vessel to another, the amount of benefit is readily ascertained, as well as from the appearance of the patient and the diminished frequency of his pulse. After a variable time solid faeces are discovered, and the products of ulceration are no longer found. The enemata may now be discontinued, and the opium by the mouth gradually reduced. The bael should be persevered with for an indefinite time, as it is a useful tonic to the mucous membrane, and a regulator of the alvine evacuations.<sup>4</sup> The return to ordinary diet must in all cases be slow and cautious. I have generally found my patients able to eat a little tender meat before they could venture upon vegetables, of which latter the bael supplies the place, and this remedy is particularly advantageous when there is any scorbutic taint.<sup>5</sup>

The treatment I have just described is that which I have been accustomed to use for adult males. For delicate women or younger persons the doses of ipecacuanha and other things must be proportionally smaller. Fifteen or even ten grains of ipecacuanha I have often found sufficient for women. For children about thirteen months old, three or four grains of ipecacuanha with half a grain of compound kino powder act quite as favourably as the larger doses upon adults. Teething is often a powerful factor in these little patients, and great relief may be afforded by lancing the gums. In my experience the ipecacuanha treatment has not answered well in children much under a year. Up to ten months, at any rate, they do not bear well the nausea and starvation it involves. Children that are nursed, however, are not very liable to severe dysentery; it is the hand-fed children that give trouble. Up to about ten months I have found calomel answer better than ipecacuanha. For mild cases very small doses are sufficient, and an enema containing one or two minims of tincture of opium. In the more severe cases half a grain of calomel may be given, morning and evening, to a child eight or ten months old, and the enema twice in twenty-four hours. I have never found leeches necessary for a child, nor have I ever had to treat children in the stage of ulceration, as they have always recovered or succumbed before this has been reached. In young children I have been accustomed to stop all farinaceous food, and, except in infants at the breast, to limit the milk very much, giving beef-tea or chicken broth instead.

As to the amount of opium to be given in dysentery, this must depend upon the case. Adults will sometimes take an enormous quantity without producing narcotism, perhaps because it rapidly passes out of the body. So also with children; having begun with one or two minims in the injection the quantity may sometimes be increased far beyond what a child would be expected to bear.

In almost all cases of acute dysentery, both adults and children, I have of late years adopted the system above recommended of administering the medicines every twelve hours. The effect of a large dose of ipecacuanha lasts fully

this time, and the long interval favours rest, which is especially desirable in a disease so strongly characterised by its absence. Occasionally I have departed from the system to the extent of giving four small enemata in twenty-four hours; in other cases, when the vomiting from the ipecacuanha has appeared to cause expulsion of the small enema from the rectum, I have given this in the middle of the twelve-hour period instead of at the end.

Thus far I have drawn the favourable side of the picture. Of the unfavourable cases I have little to say. When the stage of ulceration has been reached, the large enema sometimes fails to give relief, especially in persons past the middle period of life; the evacuations do not improve, the pulse becomes quick and feeble, emaciation proceeds rapidly, and the patient soon becomes too weak for anything but palliative treatment. In these the large enema must be discontinued, but the small enema, the bael fruit, mild doses of quinine, mineral acids, and opium should be persevered with, and may lead to eventual recovery. When the strength admits, large blisters over any obviously thickened part of the large intestine are sometimes decidedly beneficial.

The point at which acute dysentery ends and chronic begins is difficult to mark accurately; but of those cases that have continued under my care, I do not remember any resulting in the chronic form since I began to use large doses of ipecacuanha.

From first to last only a few cases of chronic dysentery have come before me, and these were at the General Hospital in Calcutta previous to 1861. I treated most of them, if not all, with the large enema, but the records are not now in my possession. The greater number were invalided soldiers, who remained in Calcutta till ships were ready to convey them to England.

The above observations have been drawn from European cases. The treatment of the natives of India is the same as regards medicines by the mouth; but otherwise it is different, and in the stage of ulceration it is generally unsatisfactory, as they object strongly to enemata of every kind.

Oxford-gardens, North Kensington, W.

## ABSCESS OF THE SPLEEN TERMINATING FATALLY THROUGH PERFORATION OF THE STOMACH.

By WM. H. BULL, F.R.C.S. ED., L.R.C.P. LOND.,  
SURGEON TO THE STONY STRATFORD HOSPITAL AND  
DISPENSARY, ETC.

GEORGE D—, aged forty-two, a groom, married, with five children, presented himself at the Stony Stratford Dispensary on Thursday, Dec. 29th, 1881, with the following history.

His family history was very good. Was very healthy as a boy; had never had any illness. At the age of nineteen he entered the army, and was sent with his regiment the following year (1861) to India. There he remained for nine years, during which time he suffered from inflammation of the liver, and what he called "the fever," and had several attacks of ague. Was discharged from the army for ill-health, and returned to England early in the year 1870. While in India he was of very temperate habits, and when discharged received a certificate of extra good character. Upon his return to England he married in 1871, and became teetotaler for the first twelve months, after which he took to drinking, and has been a heavy drinker, more or less, up to the present time. Since his return from India has often complained of not feeling well, and constantly suffered from pain over the spleen, but has never had a return of ague. In 1875 he suffered from a very bad ulcerated throat, which had to be freely cauterised. In 1877 had another attack of the same kind, and shortly after that he suffered from inflammation of the lacrymal sac; this terminated in an abscess which burst and discharged for many months, and he got into a very low, weak state. He ultimately picked up again, and has enjoyed better health for the last two or three years. There is no history at all of syphilis, and no traces of that disease. For the last month he has been feeling very poorly, without any definite symptoms; has been extremely irritable, and on several occasions most impertinent to his master, his previous behaviour having been most exemplary.

<sup>4</sup> Indian Pharmacopoeia, p. 46.

<sup>5</sup> See Dr. T. E. B. Brown's remarks on the Indian Pharmacopoeia, Indian Medical Gazette of Dec. 1st, 1877, p. 309.

**Present illness.**—On Thursday morning, December 29th, 1881, he got up at the usual hour and went to the stables at 6 A.M., feeling very poorly. At 7 A.M., on his way to breakfast, felt very sick, and suddenly vomited (according to his statement) at least half a pint of blood. This seemed to relieve him, and he felt better and more comfortable when he walked to the dispensary at 9 A.M. than he had done for some time. He was pale and anæmic and a good deal emaciated. On examining the abdomen, in the epigastric region immediately below and slightly to the left of the ensiform appendix there was a spot the size of sixpence, tender only on great pressure; the rest of that region was perfectly free from pain. The liver extended to the lower border of the eleventh rib. The spleen was apparently of normal size, and no pain or discomfort was experienced on pressure in that region. The thoracic organs were all perfectly healthy. The pulse was quiet, regular, rather weak, 76 per minute. Bowels constipated, and had been so during the last few days. He was ordered immediately to bed, with nutritious liquid diet (cold), and ice to suck *ad libitum*. Perchloride of iron, with morphia, was prescribed. On his return home that morning, contrary to orders, he went to the stables and attempted work, but, feeling so weak in the afternoon, was compelled to go to bed. Feeling still very poorly, he remained in bed the two following days (Dec. 30th and 31st), but got up on the third day (Jan. 1st, 1882), and being much better in all respects, went to work on Jan. 2nd, having had no pain during the last three days.

Jan. 3rd: Went to work as usual in the morning, but was so cold and thoroughly exhausted that at midday he went home and retired at once to bed.—4th: Passed a comfortable night, but woke early, feeling very sick, and at 7 A.M. vomited quite ten ounces of blood. Ice was freely given, and the usual treatment resorted to, after which he felt very comfortable. About 9 A.M. passed a very copious stool composed principally of blood. Nausea came on again in the afternoon, and at 3 P.M. vomited at least a pint of blood, after which he experienced considerable relief.—5th: Passed rather a restless night. Has had no sickness or nausea at all to-day, but complains bitterly of dreadful exhaustion and prostration with a good deal of troublesome headache; bowels acted once, composed of faeces and blood; has taken nourishment well.—6th: Passed a very restless night, being a little delirious at times. Early in the morning he had a severe rigor, which lasted twenty minutes; after the rigor had passed off he felt very sick, and suddenly vomited a pint of blood, which gave intense relief. In the middle of the day two large solid lumps of blood-clot passed the bowels. In the evening had another rigor similar to that in the morning; but this was not followed by nausea.—7th: Passed a better night but is very weak and prostrate; in the morning felt very sick and vomited ten ounces of blood, principally in large clots; this gave considerable relief, and he felt comfortable for the rest of the day.—8th: Passed a comfortable night. At 10 o'clock A.M. was seized with a most severe rigor lasting over twenty minutes, which left him so utterly exhausted that he never rallied, and in spite of all treatment got rapidly worse and died at 10 P.M., being conscious up to the last few moments of his life.

**Necropsy of body, thirty-six hours after death.**—Body a good deal emaciated, but free from marks and scars. Examination of abdomen: The liver was somewhat under normal size; the peritoneum covering it was more or less adherent throughout, especially on its upper surface, and in parts there were firm adhesions to the under-surface of the diaphragm. The organ was pale and firm, presenting on section a waxy, and in parts a somewhat nutmeg, appearance. On removing the stomach an abscess was found, the size of a small orange, in close relationship with the splenic extremity. This abscess was bounded in front by the splenic end and posterior surface of the stomach; on the outer, or left, side by the lower end of the spleen; below by the pancreas. It had perforated the stomach just where the splenic extremity and posterior surface meet, in four places; one of them freely admitted the index finger, two others admitted the little finger, and the fourth the top of a penholder. The lower part of the largest perforation was much thickened, and seemed to be in a most acute stage of ulceration. A medium-sized branch of the splenic artery, which ran by its side (on the posterior surface of the stomach), presented a perforation large enough to admit a very small pocket-case director; this perforation of the artery was situated just inside the abscess cavity. The abscess contained about an ounce of thick, dark, grumous matter. The mucous

membrane of the stomach adjacent to these perforations was very vascular, and the veins gorged with blood, but that covering the rest of the organ was of natural colour, though very anæmic. The stomach contained about ten ounces of dark, thick grumous matter, the same as that found in the abscess; it was about the consistence of cream. The spleen was soft and pulpy, and almost broke down on removal; its substance throughout was of a deep brick-red colour, and seemed to present one homogeneous mass, which was of about the consistence of brain matter. Its lower part was entirely disintegrated, and in a state of ulceration, forming the outer boundary to the abscess wall. The pancreas was healthy; at the splenic end its upper surface was thickened, and entered into the formation of the abscess. The kidneys were of normal size, very pale, but quite healthy. The cap-

Portion of stomach, showing the perforations; outer surface; a is a glass rod passed through the artery at the seat of perforation, the tissues surrounding which have been dissected sufficiently to expose the artery.

sules were easily removed. All the other organs were found perfectly healthy. The head, at the request of the friends, was not examined.

**Remarks.**—This case seemed to be clearly one of "ulcer of the stomach, with death from perforation." The appearance of the patient, his emaciated condition, his age and history in general made me strongly suspect that the ulceration was of a malignant type. The post-mortem examination, however, showed that perforation was secondary to abscess in the spleen. This abscess in perforating the stomach from without inwards had also perforated an artery; thus the cavity had been acting as a reservoir for the blood, which was discharged thence into the stomach, and this accounted, no doubt, for the somewhat long intervals between the vomitings of blood. With regard to the etiology, it is not improbable that hæmorrhagic infarction occurred during one of the patient's attacks in India, which had remained latent up to the fatal illness, and that consecutive inflammation and suppuration of the spleen were now accelerated by his intemperate habits and failing health.

**APOTHECARIES' HALL OF IRELAND.**—The following office-bearers have been elected for the ensuing year: Governor: Thomas Collins. Deputy Governor: R. Montgomery. Court of Directors and Examiners: E. H. Bolland, John Evans, A. Harvey, Charles Holmes, Charles Henry Leet, Charles Frederick Moore, Henry P. Nolan, Richard O'Flaherty, Edward O'Neill, George Bolster Owens, John Ryan, James Shaw, and George Wyse. Representative on the General Medical Council: Thomas Collins.

**SANITARY INSTITUTE OF GREAT BRITAIN.**—The fifth Autumn Congress and Sanitary Exhibition of this institute will be held at Newcastle-upon-Tyne on September 26th to 30th, under the presidency of Captain Douglas Galford, R.E., C.B., F.R.S. Prof. de Chaumont, M.D., F.R.S., has consented to give a lecture to the Congress.

## ON A CASE OF ABDOMINAL ANEURISM.

By S. M. SALAMAN, M.D.,  
SUPERINTENDENT, DECCAN CENTRAL GAOL, POONA;  
AND  
E. D. MACKELLAR, M.B.,  
POONA.

R. G—, Hindu, aged thirty-three, height 5 ft. 6 in., was admitted into the hospital of the Deccan Central Gaol on August 24th, 1880, and died on September 19th, 1880. At the time of entrance into gaol (four months before admission into gaol hospital) he weighed 90 lb. After death he weighed 71 lb. When he came into hospital he was a spare man, yet his condition must not be inferred from his weight according to European standards, as a Deccan Hindu of 5 ft. 6 to 8 in. may be in perfect health, and yet weigh no more than 100 lb. The patient sought for medical treatment on account of a painful throbbing lump in his abdomen. The pain, he said, was constant, but subject to irregular exacerbations. He stated that he had seen no lump, and felt no pain or throbbing till after his admission into gaol; but much importance cannot be attached to this assertion, as natives of his condition are usually wanting in exact observation, and, as a rule, are unwilling to make clear and consecutive statements about their ailments.

On examination, a smooth rounded swelling was seen a little below the inferior margin of the liver and rather to the right of the middle line. The swelling was somewhat of the same size and shape as the larger end of a hen's egg. It appeared to rise and fall with the pulse of the abdominal aorta. The skin covering it was unaltered and free. The percussion note was dull. Manipulation showed that the tumour was much larger than might have been supposed from mere inspection. It extended far to the right and considerably to the left of the middle line. Though it could not be entirely isolated, it could be freely grasped, and gave the sensation of forming a mass of sufficient size to fill the hand with the fingers moderately extended. It allowed of little or no motion in the axis of the body, but it could be moved with ease from side to side. It had the feeling of being firm, smooth, and widely lobed. Though it rose and fell so regularly with the movements of the aorta, it was altogether free from any eccentric expansion. Five days before the patient's death it became smaller, firmer, and less movable. The inferior margin of hepatic dulness was normal and demarcated from the tumour by a well-defined space that gave a tympanitic note on percussion. The only other abnormalities that could be seen were a general atheromatous condition of the visible arteries and a hydrocele of the right tunica vaginalis. There was no cardiac or local murmur, no difference in any of the pulses, no oedema or paralysis of the lower extremities. The patient's strength rapidly sank after his admission into hospital, and at the time of his death he was in a state of great emaciation. There seemed to be no other cause for this rapid loss of strength but the local one, as the patient was in other respects free from any marked complication till shortly before death, when subacute dysentery supervened.

On post-mortem examination the tumour was found to be an aneurism of the abdominal aorta situated below the celiac axis and embraced by the head of the pancreas. The sac was adherent to the surrounding organs and tissues, in some parts so loosely that the handle of the scalpel was sufficient to break down the attachments, in others so firm that a more or less careful dissection through the tissue of new formation was required to separate the tumour. The small intestine was the only structure that showed signs of having suffered from pressure. At one spot, though not adherent, it had become semi-gangrenous, and at another it was so firmly attached to the aneurism that it could not be set free without injury, and the central portion of the implicated intestinal wall was discoloured, softened, and almost eroded. The aneurism started from the anterior aspect of the aorta and the spine was not interfered with. As the tumour was adherent to parts that naturally allow of a considerable amount of play, its own free movement was not difficult to understand. The neighbouring arteries were unusually patent. The wall of the left ventricle of the heart was

markedly thickened. The valves were normal. The arch of the aorta was atheromatous, but presented no calcareous plates. The pleuræ of both lungs showed old adhesions. The liver was much congested. The large intestine was affected with severe and generalised dysenteric inflammation and ulceration. When the aneurism was removed from the body its contour was found to correspond with the idea formed of it during life. It measured 4½ in. in length, 2½ in. in breadth, and 2½ in. from before backwards. When cut into it was seen to be filled with stratified blood-clot of the consistence of the parenchyma of a healthy liver. The mouth of the sac measured 2½ in. in length and 1 in. in breadth. The clot in this situation was paler and firmer than that within the body of the sac. It sank slightly below the level of the unaltered arterial coats, thus increasing to a small extent the lumen of the aorta at this point. Its exposed surface was sufficiently smooth to interfere but little with the blood-current. Throughout the greater portion of the wall of the aneurism the arterial coats could be traced, but at points considerable thinning had taken place, and the parietes were reduced to a single yielding layer of connective tissue.

Perhaps the above case may be of interest from the fact that it presented some of the points that usually indicate that a tumour is not an aneurism, and that it appeared just to have missed a spontaneous cure. Possibly, too, it is worth remembering that the tumour could not be moved in the axis of the aorta. It may be added that at the beginning of the post-mortem examination a small incision was made through the abdominal parietes and the hand carefully inserted, with the object of ascertaining if any remedial measures might have been taken during life, but so far from this exploration throwing any additional light on the nature of the case, the true condition of things was not fully made out till the tumour was exposed and removed. The aneurism and the adherent parts, though movable *en masse*, had become so matted together that diagnosis without dissection was impossible.

## ON A CASE OF RAPID LITHOTRITY.

By THOMAS WRIGHT,  
SENIOR SURGEON, GENERAL HOSPITAL, NOTTINGHAM.

MR. G. H—, aged forty-six, farmer, applied to me in the latter part of last year with symptoms of stone, having suffered from similar symptoms for more than a year previously. On examination by a sound a calculus was detected which was believed to be suitable for removal by this method, all other conditions being favourable with the exception of a small meatus.

Nov. 13th.—The patient having been prepared, chloroform was first given and ether substituted after unconsciousness had been arrived at. Placed upon his back with his knees raised, the orifice of the urethra was slit up, and the ordinary lithotrite introduced. Crushing the calculus prior to the withdrawal of this instrument had been considerably accomplished, its size being declared when first seized to be above the average, the breaking giving evidence of its hardness. By a tube (No. 14½) a large quantity of debris was removed. Four more crushings were effected with the scoop-lithotrite, each crushing being followed by the introduction of the same tube for the extraction of pieces. At the end of forty-five minutes the bladder was found to contain nothing tangible. No blood was withdrawn, nor was the water tinged during the operation. Weight of calculus 112 grains; lithic acid. In the evening the temperature was 98° 8'. No tenderness or pain complained of beyond soreness in the urethra.—14th: Temperature 98° 6'. Passed water seven or eight times in twenty-four hours; total quantity two pints. Vomited once from anæsthetic. Evening: Temperature 100° 2'. Urine was passed more frequently, and the urine had an unpleasant odour, besides being slightly tinged with blood. No pieces had been seen.—15th: Urine less odorous, and free from blood. Passed two pints and a half of urine. Took food well, and general condition admirable. Soreness of urethra much less. Evening: Temperature 100° 8'. Discomfort in bowels. Enema was ordered.—16th: Temperature 98° 8'. Enema had acted well; urine passed much less frequently. In the evening the patient became very nervous and complained of pain in the left iliac fossa, which

was believed to be due to flatus. Temperature 100° 2.—18th: A normal temperature was recorded and a good night. Sat up for an hour. Evening: Temperature 100°. Urine slightly turbid on cooling. An enema ordered.—19th: Bowels acted naturally. Temperature normal. Complained of hæmorrhoids. From this date nothing material was noted, and the patient returned to his home on Nov. 25th.

*Remarks.*—In a highly nervous and sensitive man a stone of fair size was thus removed with ease, and followed by no discomfort nor untoward circumstance, showing clearly that in this method we have a means of affording relief to our patients much less dangerous to the sufferer than lithotomy, and more palatable to the friends.

WON, J. M. D. LOND.

## CHILD BIRTHS IN GENERAL PRACTICE.

By CAREY COOMBS, M.D. LOND.

SOME time ago in a leading article in THE LANCET a regret was expressed that the statistics of childbirth were so difficult to obtain. I was reminded of this by an application from the Registrar-General's office for details of a death occurring in my practice which was connected with pregnancy, so I have summarised my cases, and have compared the numbers with the total births. A country practice is not bounded by an exact line, but I should have been called in to any difficult labour, or one that was likely to prove fatal, within a certain area, during the past ten years. The number of births in that period, in a population of 4900, has been 1350, or nearly, of which number 660 have been attended by me and my assistants. The number of deaths in childbed during the same period has been about eight. The causes of death in these cases have been as follows:—

CASE 1.—Mrs. S—, aged forty-six, a flabby woman, in her ninth confinement, was first seen by my assistant, but the presentation was so high up after several hours of labour that he sent for me. I found the child's face presenting, and turned with some difficulty, because the membranes had ruptured twenty-four hours before, and because the pelvis was narrow the extraction of the head was very troublesome. This patient died from phlebitis about five weeks later.

CASE 2.—Mrs. C—, aged about forty, with a rather narrow pelvis, was delivered naturally of a live child after three hours of very strong expulsive pains. Eight days afterwards she was seized with pain in the bowels and faintness, and died in an hour or two. There was no autopsy.

CASE 3.—Mrs. W—, aged thirty-seven, was attended by my assistant in her fourth confinement. The child was born easily, but the placenta was adherent, and very fragile, and he had much difficulty in removing it. This patient sank after four weeks of pelvic cellulitis.

CASE 4.—Mrs. M—, aged over forty; in her ninth pregnancy. She had hæmorrhage every month. At the sixth and seventh months the amount of discharge increased, and at the eighth month, when the hæmorrhage had been going on for thirty-six hours, I was asked to see her. The placenta was not so completely over the lower part of the uterus that I had to detach it in dilating the os. The turning presented no special difficulty, but the extraction of the head occupied much time. This patient did well for a few days, but died of septicæmia about fourteen days after her delivery.

CASE 5.—Mrs. B—, aged about thirty-six. This woman was feeble and anæmic, had had several miscarriages, and died in her third full-time confinement from hæmorrhage. Her attendant told me that she had a good labour; the flooding came on soon after he left the house, and was fatal within two hours of the delivery.

CASE 6.—Mrs. F. F—, aged forty-four, an imbecile and a drunkard; she had lived under unfavourable circumstances during her pregnancy, with little food and much beer. In the ninth month she had frequent discharges of blood; and when seen at 8 A.M., and subsequently by my assistant was very weak—there was no uterine effort. When I saw her, about 4 or 5 P.M., she was collapsed, but the discharge had ceased, the os was dilatable, the head and placenta presenting; there were no pains, and there was no pulse worth mentioning. We tried to make her rally by the use of external heat, frequent warm nourishment, the subcutaneous

injection of ether, and transfusion, but I need hardly say that no attempt was made to deliver a woman in so low a condition. We remained with her till her death, at 11 P.M.

CASE 7.—Mrs. R—, aged twenty-five, was attended in her fourth labour by a midwife, who desired the husband to go for me as his wife was flooding. When I reached the house I found a fine young woman quite dead, with her uterus and the attached placenta lying in the bed.

CASE 8.—Mrs. P—, aged about thirty-two. As I sat in the room, attending her in her fifth confinement, I was annoyed by a decided smell of sewer-gas. As it appeared that a closet had been made in a corner of the room, in such a manner that the cesspool of the privy could send its gases into the room, my patient was removed as soon as possible, and the insanitary closet was stopped up. My patient had a good labour, but died twelve days after from septicæmia and meningitis.

In 1000 confinements there have been 13 cases of placental presentation, 20 infants have presented the breech, 12 the feet, and 13 the arm or shoulder. The last case of this kind was spontaneously evolved before I could see the patient. There were 7 cases of face presentation. In 2 instances there was mania. Three patients were convulsed, but none of them died. The long forceps were applied in 35 cases; short forceps in 52 cases; making a total of 87. In 21 cases version was required, and in seven cases the infant's head was opened. Two of these craniotomies were done in consultation, as were one or two of the versions; but the statistics generally apply to cases attended by myself or my assistants. I wish to call attention to the large number of placental presentations. Those occurring among farmers' wives appear to be due to the long periods, often many hours continuously, which they spend standing in the dairy. This laborious work is often continued throughout the pregnancy.

In conclusion, then, it appears that not half the child-births are attended by a medical man, and the calculation of the percentage of deaths must be based upon the total number of deliveries; eight deaths in 1350 confinements are equivalent to one in 168½. I find some difficulty in enumerating the cases of flooding, because this symptom is so hard to define; but if the hæmorrhagic cases, placental, accidental, and post-partum, were added to others in which manual interference was required, and to the cases requiring delivery by forceps or the perforator, the proportion of purely natural labours would seem small as compared with those occurring in the practice of some men who have published their statistics.

Castle Cary.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

### WESTMINSTER HOSPITAL.

ULCERATIVE (? SEPTIC) ENDOCARDITIS SIMULATING  
ENTERIC FEVER; DEATH; NECROPSY; REMARKS.

(Under the care of Dr. STURGES.)

FOR the following notes we are indebted to Mr. E. Carroll, clinical clerk.

Sarah E—, aged thirty-nine, was admitted on June 13th, 1882. She was married, and had had one living child and three miscarriages, the last two years and a half ago. She had been a healthy woman till two months before admission, had lived the greater part of her life in London, and of late had occupied herself in household work.

Two months before admission she began to feel ill, her appetite failed, she had pain in the chest and between the shoulders more or less constantly; she also had pains, which she described as "rheumatic," affecting first one limb and then another, and was under treatment for this. No more definite symptoms showed themselves until three days

before admission, when she took to her bed feeling "feverish," without diarrhoea, vomiting, or cough.

On admission the patient looked pale and ill. The tongue was rather tremulous, and covered, except at the edges, with dirty, yellow, moist fur. (The tongue remained in this condition all through the illness, and never became dry or brown.) Skin moist; pulse 96. Urine acid; no albumen; specific gravity 1015. Chest: Heart apparently normal in position and action; no bruit; breath-sounds natural. The abdomen was not tumid or tender; no gurgling; no enlargement of liver or spleen; no pain complained of; no dyspnoea; no diarrhoea. The patient complained principally of languor, want of appetite, and debility. The temperature on admission was 100°; next morning 103.6°. Liquid diet, milk and beef-tea.

June 15th: Left pupil larger than right; tongue still furred, slightly drier. Temperature last night 102.6°; pulse 108. Ordered five minims of dilute hydrochloric acid three times a day.—17th: Temperature for last two days has varied considerably—on the 15th, 99.2° to 102.4°; on the 16th, 101.4° to 104°; on the 17th, 97.6° to 102.4°.—20th: Bowels have been opened occasionally, once every other day, till to-day. To-day two motions, resembling enteric stools in appearance and smell; no tumefaction or tenderness of abdomen; highest temperature 101.8°.—21st: Temperature still high, 102.4°. Ordered two teaspoonfuls of brandy every three hours.—22nd: Temperature 101.2° to 103.4°; on the 23rd, 101.6° to 102.4°; on the 24th, 102.4° to 103.6°. The patient is in much the same condition; complains of numbness and aching pain in left foot and leg, principally in the calf. There is no visible change in tissue; foot very cold; hot fomentations. Ordered hot bottle to foot. Bowels opened on an average twice a day; motions as before; lips very pale. Ordered two teaspoonfuls of brandy every second hour.—28th: Temperature has varied from 98.3° to 104.2°. Some slight pain in abdomen; no tenderness; tongue the same; diarrhoea continues; two motions a day.—27th: No pain in leg; stiffness.—Temperature on the 28th, 99.8° to 101.2°; on the 29th, 99.4° to 102.6°; on the 30th, 101.4° to 102.6°.

July 3rd: The condition of the patient much the same. Ordered one grain and a half of sulphate of quinia, eight minims of dilute hydrochloric acid, in water, three times a day. Brandy continued.—5th: Condition still unsatisfactory. Heart and lungs examined; nothing abnormal found. Slight cough; bowels the same; tongue still furred and moist. Temperature 100° to 103°; pulse 116.—8th: The quinine mixture increased to two grains; brandy continued. Pulse more rapid and feeble; tongue still furred, moist, and tremulous. The heart-sounds normal; a few rhonchi over left chest, in front. Brandy omitted. Temperature 99.2° to 103.6°.—19th: The patient had well-marked rigor early this morning, lasting forty minutes; condition appears critical. Respiration rapid and shallow, 40; skin cold and clammy; lips pale. Very feeble, complains of nothing definitely, quite sensible; no bruit heard; no dulness over chest; a few rhonchi at bases; pulse 150. Ordered six ounces of brandy in twenty-four hours.—10th: The patient has gradually sunk into a great collapse; legs drawn up; no distension or tenderness of abdomen. Temperatures 98°, 97°, 96.4°, and 95.8°. Almost pulseless at wrist; lips very livid; face much cyanosed; cold clammy sweats, occasionally delirium. Champagne ordered; was sick after three doses; brandy, hot bottles.—11th: The patient died at 2.30 this morning, in a state of great collapse. Last temperature taken, 95°.

*Necropsy.*—Body well nourished; rigor mortis persistent. Brain, pleura, lungs, and pericardium normal. All the cavities of the heart were distended with decolorised fibrinous clot; the muscular tissue was pale, and that of the right side much paler than that of the left. The wall of the right ventricle was very thin, in some places not exceeding  $\frac{1}{8}$  in.; there was over the apex a thickish layer of subpericardial fat. The aortic valves were the seat of ulcerative inflammation, which in places exhibited perforation. Connected with the same valves were large vegetations. One valve was divided by the ulcerative process as far as its base, while from a second an oval mass of old fibrinous clot, about an inch in length, depended from a thin pedicle; this valve also had a small perforation about its centre. On the remaining valve was a conical vegetation about the size of a small pea. All the vegetations were on the ventricular aspect of the valves. Spleen and intestines normal. Careful search was made for emboli, but none were discoverable in any part of the body.

*Remarks by Dr. STURGES.*—The above case is of interest

as a contribution to the clinical history of an affection which is at present classified under two headings: the typhoid and the pyæmic. It is a striking illustration of the former. Not only were the symptoms of enteric fever very closely imitated, but there were circumstances of the patient's history referring to defective drainage in the house whence she came which pointed in the same direction. It will be seen that after remaining for three weeks in the condition described with no very threatening symptoms the patient, on what was reckoned the thirtieth day of the fever, had a severe rigor, after which she became collapsed, and rapidly sank. It was thus only a few hours before death that any symptom occurred to bring the case within the definition of septic fever. With such an ending, however, had the physical signs lent their aid we might have had the satisfaction of arriving at a correct diagnosis during life; but it so happened that auscultation gave no assistance. Owing to the ambiguous character of the earlier and of the latest symptoms, the chest was carefully examined both when the patient first came under notice and when she was about to die. It may be stated positively, therefore, that the cardiac sounds were clear and without murmur. How it happened that such lesions as were found post mortem failed to announce themselves in life need not here be discussed. It is of interest to observe how the accidental absence of cardiac murmur may leave us without the means of discriminating ulcerative endocarditis from enteric fever, a disease which already has a good deal credited to it, and which we are perhaps too apt to appropriate upon insufficient warrant. Those interested in the pathology of ulcerative endocarditis may profitably peruse Dr. Coupland's cases, published in the *Medical Times and Gazette* of this year, as well as a clinical lecture by Dr. Wilks, in the *British Medical Journal*, Jan. 14th, 1882.

## GOCULDAS TEJPAL HOSPITAL, BOMBAY.

### CASES OF ELEPHANTIASIS OF SCROTUM.

(Under the care of Surgeon-Major T. CODY.)

The following cases conclude the report commenced in the "Mirror" on July 29th, and continued last week.

**CASE 4. Elephantiasis of Scrotum; Removal by Operation; Recovery.**—A Mussulman priest, aged forty-two, had a tumour involving both penis and scrotum, a growth of about ten years. In operating on this case there was some trouble in freeing the penis from the diseased structures, as there were little patches of healthy integument on both sides of it, which had to be preserved. The diseased structures on the scrotum went very high up, so that there was some difficulty in fixing the testes, both of which were found healthy and preserved, in their position. This case was operated on under the antiseptic spray, and the dressing used was a layer of carded oakum well saturated in the spray, and covered by four layers of antiseptic gauze, two of saturated gutta-percha tissue, and all applied under the spray and covered over with a piece of oiled cloth.

On the fifth day after the operation there was an erysipelatous blush over the right pubic and pelvic regions, which was painted over with a solution of the perchloride of iron. The erysipelatous redness shifted down the right thigh and leg and eventually extended to the left side and the back, lasting altogether for about five or six days, and producing little or no constitutional disturbance. Wherever it appeared it was painted with solution of the perchloride of iron, thirty drops of which were also given internally three times a day after food. After the fifth or sixth day the erysipelas disappeared altogether, and the wound progressed without a further bad symptom. When the discharge ceased the granulating surface was dressed with boracic acid ointment, under which the healing process progressed most favourably. This man was altogether about six weeks in hospital. The tumour weighed six pounds.

**CASE 5. Elephantiasis of Scrotum; Removal; Recovery.**—An old Hindoo, aged sixty-two, a carpenter, was admitted with a tumour involving the integument on the under surface of the penis (that on the dorsum being quite healthy) and the entire scrotum. It was a growth of over twelve years, and when removed weighed above eleven pounds. The left testicle was found diseased and excised, but the right being healthy was preserved. He was an excellent patient,

being perfectly indifferent to himself and his disease, and regarding what was done for him in a most philosophic manner. The result was he made an excellent recovery, and left the hospital about two months after the operation, with the wounds all healed.

ELEPHANTIASIS OF THE LABIA VULVI; REMOVAL;  
RECOVERY.

A Hindoo woman, aged thirty years, presented a most unsightly elephantoid tumour in the left labium, which extended downwards into the perineum. In the right labium there was a smaller tumour, about the size of an orange and unconnected with the first. The incision to remove the tumour on the left side extended from the mons Veneris to the end of the perineum, and was carried on the inner side through the mucous membrane on the inner surface of the labium. The incision on the outer side extended to the left groin and margin of the thigh; and when the mass, which weighed about five pounds, was removed, a most unsightly gaping wound was left. There was very little hæmorrhage, and slight torsion was found sufficient to arrest that in the three small vessels severed. The smaller tumour on the right was now removed, and the edges of the wound were brought together without any trouble. To effect healing of the first wound the legs had to be brought together and the thighs tied firmly by a broad bandage. Three or four wire sutures were put in by which the mucous membrane of the vagina and the outer integument were connected. This position, however, was more relied on to assist the healing process than anything else, and she was so kept, with the legs tied together, for over three weeks. It was most remarkable how the parts began to assume their natural shape as the healing process went on. The surface had altogether healed over five weeks after the operation, when the patient was removed by her husband.

## Reviews and Notices of Books.

*Foods, their Composition and Analysis.* A Manual for the use of Analytical Chemists and others, with an Introductory Essay on the History of Adulteration. By ALEXANDER WYNTER BLYTH, M.R.C.S., F.C.S., &c., Public Analyst for the County of Devon, and Medical Officer of Health and Public Analyst for St. Marylebone. London: Charles Griffin and Co. 1882.

ALTHOUGH this work is intended primarily for the use of analytical chemists, it contains much that will prove of value and interest to those engaged in the practice of medicine. The historical introduction is evidently the result of considerable labour and research, and it is amusing to find that the practice of sophistication was not unfamiliar to the Greek and Roman traders. In fact the adulteration of wine in ancient Athens was practised to such an extent that a special inspector was appointed to investigate the matter. In our own country, in the latter part of the twelfth century, "false weights, false measures, false pretences of all kinds were the instruments of commerce most generally in use; no buyer would trust the word of a seller, and there was hardly any class in which a man might not with reason suspect that his neighbour intended to rob him." The author's account includes a history of adulteration as practised from very early times by bakers, brewers, vintners, druggists, and others, and he also refers at some length to the history of the crime as practised in France, Germany, and other countries. The chapter on the Duty of the Inspector or Purchaser under the Adulteration Act is thoroughly sound and practical, and will be read with much interest. The advice given to inspectors is not only sound but judicious. "The official purchaser," says the author, "should not select, to the exclusion of others, the poorest shops, but take samples as equally as possible." He points out that the purchase need not be effected in an officious manner, and that it is not fair, for example, to enter a shop full of people and with ostentation buy and divide the sample before the customers.

The subject of the adulteration of bread with alum is of considerable interest to medical men. This substance is added to bad or slightly damaged flour both by the miller and baker. Its action, according to Liebig, is to render insoluble gluten which has been made soluble by the acetic or lactic acid developed in damp flour, and hence it arrests the undue conversion of starch into dextrine or sugar. The author considers that the influence of alum on health in the small quantities in which it is usually added to bread is very problematical, and that it rests upon theory more than observation. We are not prepared to say that this view is not correct, but it is certainly opposed to the observations of some recent writers on therapeutics—Phillips, for example, who says that he has often traced indigestion to alum in bread. In testing for alum the crust and crumb should be analysed separately, for many bakers use for the latter only a flour technically called "cones," which is strongly alumed.

The chapters and articles on Milk, Cream, Butter, and Cheese are written in a workmanlike manner, and are deserving of attentive perusal. A full account is given not only of cow's milk but of human milk, and of the milk of the goat, mare, ass, camel, hippopotamus, and other animals. A very interesting description is given of the milk-like secretions of birds and plants. It is by no means certain that mammals alone secrete milk, for pigeons after the young birds are hatched secrete in their crops a nutritious albuminous fluid which is used for feeding the offspring. In the vegetable kingdom many plants and trees yield a white fatty secretion popularly known as milk, but these fluids as a rule have no right to the title, being totally different both in composition and properties. Curiously enough, however, a true "milk tree" (*Brosimum glactodendron*) is found in Central America. On incising the trunk it yields an abundance of a thickish feebly acid fluid which coagulates on exposure to the air. This juice has been recently analysed by M. Boussingault, who finds that it is analogous to ordinary milk, containing an albuminous principle, a fatty principle, and sugar and phosphates. Koumiss is now so largely used in the treatment of wasting diseases that we turn to the author's account with much interest. He gives several analyses, and describes its mode of preparation by the Tartars from the milk of the mare and camel. A substitute for koumiss may be readily prepared from cow's milk, even by those who have had but little experience in such matters, and detailed information on this point would have been welcome. The custom of washing cheeses with a solution of arsenic to prevent the attacks of the fly is deserving of notice, and might serve to throw light on some obscure case of disease.

The chapters on Tea, Coffee, Cocoa, Chocolate, and Maté are full of interesting and valuable information. The different kinds of wine, beer, and spirits come in for their share of attention, arrack even not being omitted. In addition to the points we have briefly indicated, there are articles on various condiments, such as mustard, pepper, and Cayenne. It may be of interest to the rising generation to learn that sweets are much less frequently adulterated than is commonly supposed. A large proportion of the common sweets contain nothing but sugar, for the manufacturer, by careful heating and manipulation, is able to impart a quite surprising scale of colours, from the purest white to fawn-colour, straw-colour, reddish-brown, brown, and even black, by this agent alone.

The sections on Water Analysis are eminently practical, and, like the rest of the work, are fully illustrated. We have given the barest possible outline of the contents of this volume. It is thoroughly practical, and should be in the hands of every medical practitioner not fully acquainted with the subjects of which it treats.

*An Index of Comparative Therapeutics*, with Tables of Differential Diagnosis, a Pronouncing Dose-list on the Genitive Case and Memoranda concerning Clinical Thermometry, Incompatibility of Medicines, Ethics, Obstetrics, Poisons, Anæsthetics, Fees, Asphyxia, Urinary Examinations, Pharmacology, Nomenclature, &c. By SAMUEL D. L. POTTER, A.M., M.D., President of the Milwaukee Academy of Medicine, Author of "The Logical Basis of the High Potency Question," and many other essays in defence of the Milwaukee Test. Second Edition. Chicago: Gross and Delbridge. 1882.

THIS is a most amusing work, but it has been much more carefully compiled than would be supposed from a cursory inspection. The author has attempted a kind of index of treatment, a comparative review of the different modes of cure recommended by the leading authorities on therapeutics. A compilation of this description involves a great deal of tiresome and tedious work, and we should be none the less grateful to the author because on many points of nomenclature, and even treatment, his views will be found opposed to the majority of readers in this country. In the index he says: "The critical reader will, no doubt, notice under any given title the omission of some favourite remedy, and the insertion of others which to him seem less important. The compiler has been compelled to use his own judgment in regard to this, and cannot expect that the result will please all." Nothing could be fairer, and we are bound to say that the author's selection has been made with care and discretion. There are in reality very few omissions. Take, for example, the case of asthma; here, amongst other modes of treatment, directions are given for the use of iodide of potassium, opium, arsenic, belladonna, lobelia, cannabis indica, coffee, ipecacuanha, stramonium, and datura tatula, Grindelia robusta, nitre papers, chloroform, ether, nitrite of amyl, sulphurous acid, antimony, chloral, bromide of potassium, and eucalyptus. Under the head of prophylactic treatment reference is made to the necessity for avoiding the exciting causes of a paroxysm, such, for example, as indigestible food, wet feet, sudden changes in temperature, constipation, and so on. The author mentions incidentally the application of the constant current over the pneumogastric nerve. This one example, taken quite at random, will show that the work has been well and carefully done. The author apologises for the omission of all reference to certain works on materia medica and therapeutics, pointing out that the nature of the plan adopted by him precludes reference to those "who deny disease-entity or omit pathological and physiological indications for drug usage." The chapters on Ethics and Fees are of interest, although they have no special reference to practice as pursued in this country. It would have been more in accordance with our notion of the general fitness of things had these articles been relegated to a special section, and not mixed up with questions of treatment. It is rather an abrupt change from ethics to excrement, and from "feces" to fees. The alphabetical arrangement is convenient, but has its disadvantages. On the whole the work is a good one, and will be found useful for reference.

*Nitro-Glycerine in Angina Pectoris*. By WILLIAM MURRELL, M.D., M.R.C.P. London: H. K. Lewis. 1882.

THE profession are much indebted to the author of this brochure for having introduced to their notice the important power possessed by nitro-glycerine in controlling the attacks of that most painful, alarming, and fateful condition known as angina pectoris. Whatever light subsequent research may throw upon the nature of this condition, and however much its therapeutics may thereby be modified, physicians will always be ready to acknowledge the value of the two drugs, allied in composition and in physiological action—nitrite of amyl and nitro-glycerine,—and of the two the latter certainly possesses considerable advantages over the former; for

although, as Dr. Murrell abundantly proves, the action of nitro-glycerine varies in a most remarkable degree with individual idiosyncrasy, a fact that led to much conflict of testimony many years ago, it has the merits of being more stable, of being slower in producing its effects, and producing them more permanently than does inhalation of the nitrite of amyl. This is clearly shown by the author, who has been enabled to compare not only the effects of the two drugs upon the circulation, but the very striking influence produced by nitro-glycerine in increasing the flow of urine. For this latter purpose he made observations upon the amount of urine excreted at short intervals after administration of nitro-glycerine to an epispadic, and the results are both striking and interesting. The little book contains full details of several cases treated by the author, and its perusal should go far to encourage practitioners to employ the remedy in full confidence of an alleviation, and in some instances of cure, of anginal seizures.

## THE BRITISH MEDICAL ASSOCIATION. FIFTIETH ANNUAL MEETING,

*Held at Worcester, August, 1882.*

THE third general meeting took place on Thursday morning, the 10th inst., and commenced with the reading of the Report of the Medical Reform Committee by Dr. Ed. Waters, of Chester. The report referred chiefly to the recent Royal Commission on the Medical Acts, which was stated to mark a distinctive era in the history of medical reform. It was held that the Commission had conceded all that the Association had for years contended, and the aid of the Branch Councils of the Association was sought to memorialise the Privy Council and petition Parliament to bring in a Bill founded upon the report of the Royal Commission. The report was adopted, and a vote of thanks to Dr. Waters and the Committee was passed unanimously, on the motion of Mr. H. P. Symonds, seconded by Mr. Coates.

Dr. A. CARPENTER read the report of the Committee appointed to obtain restrictive legislation for habitual drunkards. It announced the approaching opening of the Dalrymple Home for Inebriates in a healthy suburb of London, and the steps to be taken to place it under the provisions of the Habitual Drunkards Act, 1879. The Committee have also issued circulars to boards of guardians, asking for an expression of opinion on the propriety of guardians having the power to detain drunkards in work-houses for the purpose of recovering from the effects of their excesses. Favourable replies had been received, and the Committee urged the members of the Association to use their influence with boards of guardians. Dr. Drysdale seconded the motion, which was supported by Dr. Gray, who expressed the opinion that the certificate might be signed by one instead of two justices.

Mr. STOKES (Dublin) then delivered the Address in Surgery. He said that the Association, as it had its birth in the "Faithful City," so it had proved faithful in many good and noble ways—faithful in removing professional jealousies and softening asperities—faithful in protecting with its broad and strong shield those who had been cruelly and unjustly attacked—faithful in its efforts to raise the social status of the profession—faithful in its attempts to extricate public opinion from the quagmires of sentimentalism and folly—faithful in aiding and encouraging the scientific vanguard of the profession. The list of advances in surgery during the last half century was a goodly one. Among these were the abandonment of an indiscriminate bloodletting in almost every form of acute disease, of a reckless use of mercury in the treatment of certain diseases, and of setons and moxæ in hopelessly irremediable articular and other diseases. Having enumerated

a goodly list of the modern improvements in surgical treatment, he singled out as topics which far surpassed in importance all others—the three “giant strides that the past half century has witnessed,”—namely, the discovery and application of anæsthetics, the restoration of diseased or injured bones and joints necessitating resection, and “the enunciation of the principle and establishment of the practice by Pasteur and Lister of antisepticism in the treatment of wounds.” Such advances may well make us feel a pardonable pride in British surgery, and give confidence in the coming triumphs of our art. As to anæsthetics, he adverted to the peril which must necessarily attend their administration, and the need for caution and the adoption of such a rule as that formulated by Mr. Hutchinson in reference to the use of chloroform in cases below six and above sixty years of age. He expressed a personal preference for ether, as economising time, as being safer, and, as a rule, being followed by less sickness and a slower return to sensibility. The best methods for administering it were those in which the air is rebreathed by the patient, and experience had not confirmed the *a priori* belief that this admixture of ether vapour and carbonic acid gas introduced an additional element of danger. After briefly enumerating the advantages of anæsthetics, and referring to Morton's priority in their application to surgical practice, he passed to the subject of antiseptic surgery, in support of which he spoke in terms of considerable force and eloquence. Naturally he referred to the address delivered by Mr. Savory at the Association meeting at Cork in 1879, where the subject had been adversely handled, and declared that when “the address is stripped of all its brilliant eloquence and rhetorical decoration” it reveals the admission of the germ theory of putrefaction, and the fact that the method of dressing employed by Mr. Savory is essentially antiseptic. Mr. Lister's recent utterances upon the value of the carbolic spray had been much misunderstood; for he did not abandon the antiseptic principles, but looked forward to obtaining more perfect means than the carbolic spray afforded. The various views of the nature of inflammation propounded by Burdon Sanderson, Ogston, and Hueter, as to whether the infective properties of inflammatory products are or are not primarily dependent on the contact of atmospheric organisms, were shown to be equally consonant with the prophylactic principle of antiseptic surgery. The weak point of the “persistent and obstinate opposition” to Listerism is the general admission of the truth of the germ theory of putrefaction; whilst Mr. Lawson Tait's “dead tissue factor” was regarded as a superfluity. “Those who advocate and practise what they are pleased to term a ‘modified’ antiseptic system, attempt, in fact, in a roundabout, clumsy, inefficient way, to do precisely what those who practise Listerism achieve by means which are the outcome of accurate scientific research. The aim in both cases is to neutralise or destroy the agencies which predispose to and produce the *materies septicæ*; in the one instance by numerous uncertain and often inefficient methods, and in the other by the unerring artillery of chemical agency.” Mr. Stokes disposed of the taunt that Listerism lacked originality by mentioning what he had himself seen of Maisonneuve's practice. He considered that ovariectomy was not the best test of the efficacy of the method; one of the best tests of its value is resection of the knee-joint; and he illustrated this from his own experience. He also related other remarkable instances of “antiseptic triumphs,” and asked whether such results could have been obtained previous to Listerian teachings. There could be but one reply—Impossible. As to its hygienic effects, he mentioned the change that had been wrought in the hospital to which he is attached in the prevalence of erysipelas, pyæmia, and hospital gangrene—when its present condition was contrasted with that which prevailed during his studentship, an experience which had been so widely repeated abroad. Mr. Stokes then defended Professor Lister and his followers for not having more recourse to statistics in demonstrating the superiority of antiseptic methods, and asked why Mr. Savory made no mention of ovariectomy when he gave the statistics of operations at St. Bartholomew's Hospital. Without himself regarding statistics with the reverential awe of some, he mentioned that at the Richmond Surgical Hospital in 600 operations performed by himself and colleagues during the past three years, the mortality was 3·6 per cent.; “and there was not a single case in which Listerism was accurately employed that was followed by any infectious disease.” He enumerated some of the directions in which owing to anti-

septics the field of surgery had been widened, severely commented on the line taken by those who wilfully refuse to acknowledge its benefits, and concluded his remarks on this head as follows: “In the interests and for the credit of British surgery it is time so unrighteous a warfare should cease. It is time that the irritating dust of an unreasoning prejudice should be swept away. It is time that one of the greatest discoveries and boons to surgery this century has produced should be universally recognised as such. It is time that its discoverer and exponent should be acknowledged as one of whom it may well be said—

‘With genius Nature joins in everlasting covenant still,  
Thy promises of one, the other fails not to fulfil.’”

In the third part of his address Mr. Stokes dealt with the method adopted for bringing about a regeneration of bones and joints, in cases of disease or injury necessitating resection, with which the names of Syme, Langenbeck, and Ollier must for ever be associated. He described the conditions under which once operations were most successful, and referred to the great advance made by the introduction of bone-transplantation by Dr. McEwen of Glasgow. Then, speaking more particularly of bone-resection, he urged its performance before any profound organic changes take place. A reference to amputation, and especially to the single flap operation of the late Mr. Carden of Worcester, closed this survey of surgery, and the rest of the address was occupied by an eloquent vindication of experimental research, and a protest against the increasing agitation that is now maintained in opposition to it. He concluded:—“I have mentioned many achievements in surgery the past half century has witnessed. Fifty years hence this great Association will, I hope, again meet here to celebrate its centenary; and my successor will, I trust, with greater ability and eloquence than I can command, tell of as great or greater triumphs than I have done. To enable him to do so we can all aid, some powerfully, others feebly; but still every unit in this great brotherhood can assist; and it should be our ambition as well as our prayer, that when the hour arrives for us to cease from our work, we may all feel, on looking back on our lives, that we have done something to that end. Something—be it great or small—in the interests of our common humanity, in the interests of our loved country, and of a pure devotion to truth, to render the science to which we have devoted our lives nobler and fairer than before.”

On the motion of Mr. TEALE, seconded by Sir W. MACCORMAC, a cordial vote of thanks was passed to Mr. Stokes for his address.

The Stewart prize of 50 guineas was then presented by the President to Dr. Vandyke Carter, of Bombay, for his researches on Sperrillum Fever. The prize was received by Surgeon-General Walker on behalf of Dr. Carter.

The annual dinner of the Association took place on Thursday evening in the Guildhall, the President, Dr. Strange, being supported by the Bish-<sup>op</sup> and the Dean of Worcester, Sir Jas. Paget, Sir Richard Temple, Sir E. A. H. Lechmere, M.P., Mr. Geo. Hastings, M.P., the Mayor of Worcester (Col. Stallard), and many others, to the number of more than 200.

The concluding general meeting was held on Friday morning, when there was a considerable attendance, in anticipation of a vote being taken with regard to the compulsory notification of infectious disease. An animated debate had taken place the day before in the Public Medicine section, and a pamphlet impugning the action of the Parliamentary Bills Committee had been widely circulated.

Dr. CARTER, of Liverpool, introduced a discussion on the Compulsory Notification of Infectious Disease. The Public Health Act of 1872 was wise in principle, regarding the medical man as the medical officer of health of every family he attended. After the passing of the Act a desire arose for notification, putting compulsion and fine upon medical men unless they notified to the sanitary authority every case of infectious disease. This rested on the assumption that medical men did not care to limit the spread of infectious disease. He was in favour of notification in the abstract, but not of compulsion. Compulsory notification had done no good, and provoked an antagonism between two branches of the medical service, which tended to check the steady onward progress which had been made under the Public Health Act. A quarter of a million of lives had been saved by the operation of the Act. Were they to introduce a new principle, which had been proved to fail, because medical officers of health wanted it? In order to test the opinion of the

Association, he proposed that a plebiscite be issued, asking whether the members of the Association did or did not agree to the principle of compulsion.

Dr. WHITTLE, of Liverpool, seconded the resolution.

Dr. LITTLEJOHN entirely objected to a plebiscite. The experiment of notification had been tried for four years in Edinburgh. The form of intimation adopted there would do much to disarm opposition. At the bottom were the words, "No immediate attention is required." If the word "no" was erased, it was understood that the case required immediate attention. The medical man in charge was made master of the situation. The public were satisfied that the clause was necessary to health, and the clause was a most undoubted success. Dr. Littlejohn concluded by moving an amendment, that the meeting declined to withdraw from the position which the Association had repeatedly taken in urging Parliament to make the notification of infectious disease generally compulsory.

Mr. DAVID EVERETT, who seconded the amendment, said that medical men were the only persons who could notify infectious disease, because they were the only persons who could diagnose it. He would safeguard the Act in every possible way, so as not to affect the liberty of the medical man in attendance.

Dr. A. CARPENTER could not agree either to the resolution or amendment, and asked whether medical men could not perform a duty without hanging round their necks penal clauses? The penalty should be put upon the householder, and the Act placed on the same footing as the Contagious Diseases (Animals) Act in this particular.

Mr. G. W. HASTINGS, M.P., said that, having introduced the Bill for the Notification of Disease, he might be allowed to say a few words upon it. His desire was that the Bill should be sent to a Select Committee. The medical profession would then have had ample opportunity of laying the whole case before the Select Committee. If the subject were not taken up by the President of the Local Government Board, he should reintroduce the Bill at the beginning of next session, in order that it might be sent to a Select Committee. Bolton was the only borough that petitioned against the Bill. Thirty-one cities and towns had voluntarily adopted the Act. No representation had been made by any town where the system was in force that it should be abolished. No objection could be made to the dual system. If the householder would not send in a certificate, the medical man would have a right to say to the householder, "If you don't, I will."

Dr. FITZPATRICK made a strong speech against the amendment, and protested against the introduction of Government compulsion and penal clauses hampering medical men in the performance of their duties. The death certificate, he contended, was not compulsory, and it was contrary to the spirit of the profession that such a system should be introduced.

A division was then taken by show of hands, the meeting having become very excited and tumultuous. The President declared the amendment carried, and was about to put it again as a substantive motion, and many members were leaving the hall, when Dr. Mahomed (London) claimed a hearing. He declared that the amendment which had just been carried embodied no statement that the objectionable clause would be removed, and that whilst all were of opinion that compulsory notification was desirable, yet few held that the medical man should have the onus of it. He therefore moved a further amendment, in the sense of Dr. Carpenter's remarks, "That this meeting earnestly desires the compulsory notification of infectious disease, but wishes to express an opinion that the compulsion to notify should be placed upon the householder, in his duty as a citizen, and not upon the doctor." Mr. Husband seconded the amendment, which was carried by a large majority, and then adopted as a substantive resolution.

The Middlemore prize of sixty guineas was presented by the President, on behalf of the Association, to Mr. W. Adams Frost, F.R.C.S., for researches in ophthalmic surgery.

Professor HUMPHRY moved the adoption of the report of the Collective Investigation Committee, which referred to the appointment of Dr. Mahomed as secretary, and the work already taken in hand largely through his personal efforts. Three inquiries are at present on foot—viz., acute pneumonia, chorea, and acute rheumatism,—and the Branch Committee were invited to propose subjects for local investigation. A large number of branches were already engaged in the work. Mr. Dixon seconded the motion, and the report was adopted, the committee being reappointed.

Mr. E. HART moved the adoption of the report of the Parliamentary Bills Committee, which dealt with the subjects of the medical officers of the militia service, the regulation of midwives by examination and registration, the notification of contagious diseases, and the withdrawal by the Chancellor of the Exchequer of his proposed tax on carriages. The motion was seconded by Mr. Leighton Jones and carried.

Dr. WADE proposed that the report of the Scientific Grants Committee be adopted, and that a grant of £300 be made for its purposes. The researches in progress, many of which were approaching completion, include one on Anæsthetics, by Dr. McKendrick; on the Functions of the Kidney, by Dr. Newman; on the Relation of Organisms of Septic Disease, by Mr. Stanley Boyd; on the Pathology of the Heart, by Dr. C. S. Roy; on Methods for showing the presence of Bacteria in Epidemic Structures, by Dr. Thin; on the Variation and Duration of the Cardiac Ventricular Systole in Man under different conditions of Rapidity, Temperature, &c., by Dr. Chapman; on the Intimate Nature of the Contagious and Acute Infective Diseases, by Dr. G. F. Dowdeswell; on the Elimination of Nitrogen, by Mr. North; on the Pathological Histology of the Bloodvessels, by Dr. Heneage Gibbes; on the Electro-physiology of the Human Nerves, by Mr. A. De Wetteville and Dr. Waller; and on the Relation between Bacteria and Surgical Disease, by Dr. Ogston. Dr. Chadwick seconded the motion, which was carried.

Dr. KEELEY proposed that the warm thanks of the members be given to the Mayor and Corporation for granting the use of the Guildhall and Music-hall.

Dr. HARRISON seconded the motion, which was adopted.

Votes of thanks were also given to the county magistrates for the use of the Shire Hall, to the Dean and Chapter of Worcester, the Philharmonic Society of Worcester, and the members of choirs of Worcester, Gloucester, and Hereford, to Mr. Done, to Earl Beauchamp for his invitation to the garden party, and to Dr. Strange and Mr. Hastings for the invitation to the *soirée*.

Mr. E. HART proposed, in the name of the 800 members who had attended the meeting, a vote of thanks to the President, for the preparations he had made in anticipation of the meeting, his hospitality, and his able address. Never had a president performed his duties with more efficiency and urbanity.

Dr. STEWART, in seconding the motion, said that Dr. Strange was one of the highest authorities on sanitary science, and referred to a paper written by Dr. Strange on the subject thirty years ago.

A vote of thanks was then given to the Hon. Local Committee, and the proceedings terminated.

On this day a large number of members availed themselves of an invitation to visit Droitwich and its brine baths. They were there entertained at luncheon, and the little town was adorned with bunting and banners in honour of the occasion. In the afternoon a large gathering of ladies and gentlemen assembled at the beautiful seat of Earl and Countess Beauchamp, Madresfield Court, Great Malvern, where a garden party was given by the noble owners, who received their guests as they entered the grounds. In the evening a musical *soirée* was given by the President of the Association and Mr. George Hastings, M.P., in the Shire Hall, to the members of the Association and their friends.

Saturday was devoted to excursions, which were well planned, and successfully carried out, the beautiful weather adding greatly to the success of these expeditions. One party visited the Malvern hills, where the geological structure of the hills and surrounding country was explained by the Rev. W. S. Symonds, F.G.S., and G. N. Piper, Esq. Another party proceeded by rail to Ross, and thence by the Wye to Monmouth, or by rail to the same place, Tintern, and Chepstow. A third excursion was to Stratford-on-Avon, and thence to Leamington, where one hundred members were entertained at luncheon by the local members; from Leamington by carriage to Kenilworth, and thence to Warwick.

## THE SECTIONS.

### SURGERY.

At the second session of this section two important subjects were the main topics of discussion—the surgery of arteries, and abdominal surgery.

Mr. BRYANT related a case of Double Popliteal Aneurism, of which one was cured by pressure, and the other by Speir's artery constrictor with antiseptic (not aseptic) precautions.

Mr. THOMSON related the History of his case of Ligature of the Innominate Artery for subclavian aneurism, and showed the specimen. Subsequent speakers were quite agreed that the fatal result was not dependent upon the ligature of the artery, but was due to ulceration of the drainage-tube sinus, probably opening up the vertebral artery; the ligature (of aorta) had acted perfectly. The experience of this case was held to be encouraging, but it left open the question whether in another case it would not be well to ligature the vertebral artery at the same time as the innominate, even if not the common carotid artery as well.

Mr. A. H. DOLMAN reported a Case of Traumatic Axillary Aneurism successfully treated by ligature of the subclavian artery. So much difficulty was met with in getting the thread around the artery (the left), that the clavicle was divided to expose the vessel.—Mr. BARWELL showed the Aneurism Needle he had had made for cases of this kind, and expressed his belief that had it been employed division of the bone would have been unnecessary.

Mr. BARTLETT read a paper on five cases of Ligature of Large Arteries. One was a case of femoral aneurism, for which he tied the common femoral trunk with chromic catgut; the wound did not remain aseptic, and secondary hæmorrhage came on. The wound was then opened up, when it was found that the artery had separated one-tenth of an inch above the ligature. The two ends of the vessel were then tied with a hempen thread. Again there was repeated secondary hæmorrhage, for which the external iliac artery was ligatured with whipcord, with a final successful result. This case presented many features of great interest from a practical point of view, and would in itself have afforded ample material for a good discussion.

Mr. BENNETT MAY related a case of Ligature of the External Iliac Artery and discussed the best material for ligatures, and stated that there was more difficulty in getting primary union of a wound when chromic catgut was used than when carbolic gut was employed, and he expressed his preference for common catgut soaked for a long while in carbolic oil.

Mr. ROBSON showed an apparatus for obtaining an antiseptic atmosphere to replace the carbolic acid spray in surgical operations. Asserting that while the carbolic acid spray was aseptic, it was not antiseptic, and was also harmful, Mr. Robson advocated the value of an antiseptic, dry, non-poisonous atmosphere. This he obtains by pumping air through cotton-wool to purify it from all suspended impurities, and then through eucalyptus oil. To show the antiseptic value of an atmosphere of this kind, he had taken several large, wide-mouthed glass jars and poured a little of one of these oils into each, and had then suspended jars of sterilised hay infusion in them, and had removed their cotton caps for various periods; in every instance except one bacteria had not subsequently developed in the infusion. He had also used it for surgical purposes, and Mr. Spencer Wells had employed it during the excision of a mamma, and had expressed himself pleased with it.

Mr. R. H. B. NICHOLSON recorded a successful case of gastrotomy.

Mr. GEORGE ELDER related a successful case of nephrotomy and nephrectomy for scrofulous pyelitis.

Mr. LAWSON TAIT showed a girl from whom he had excised a kidney through the linea alba; he also showed the kidney, which was sacculated, and contained a large calculus.

Dr. CULLINGWORTH related a case of nephrectomy by abdominal section for hydronephrosis, in which the patient died from shock twelve hours after the operation; and in reference to this case Mr. TAIT remarked that he should never attempt nephrectomy for renal cysts, as the operation of incising and draining these cysts proved so successful in his hands.

Mr. LAWSON TAIT recorded a third successful case of cholecystotomy, and showed a large number of gall-stones he had removed from the gall-bladder. The gall-bladder formed a prominent abdominal tumour, and it was an interesting feature of the case that although the cystic duct was completely obstructed, there had not at any time been jaundice. He opened the gall-bladder, and stitched the edges of the wound in it to the abdominal incision, and extracted a large number of stones. The discharge had continued mucous until that week, when bile had made its appearance, showing that the duct had become patent again. Mr. Tait therefore intended to freshen the wound, and close the sinus.

Mr. LAWSON TAIT then read a paper on 100 Consecutive cases of Ovariectomy performed during the last thirteen or fourteen months, and in which he had not used any kind of antiseptic measure. Of these, three patients died, one from choking during vomiting, and two from venous thrombosis starting at the pedicle and spreading quite up to the heart. Six of the patients were pregnant at the time of operation, one in addition had acute peritonitis—all got well; one of them miscarried, and five were delivered of living children at term. Four patients had acute peritonitis at the time of operation, and all recovered. In two the tumour was solid fibroma of the left ovary; in ninety-eight it was cystoma. Of the latter eleven were parovarian cysts, sixty were cysts of one ovary only, and among these were the three deaths, and twenty-seven were cysts of both ovaries. In fifty-three cases there were serious adhesions, but he had not found that this fact in any way added to the mortality. Of the three fatal cases there were no adhesions in two, and slight parietal adhesions in the third. In seventeen cases the tumour was sessile. All these cases were dressed with dry absorbent cotton-wool; in about one-twentieth of the cases a part of the wound opened, and then it was dressed with zinc ointment or red lotion. Mr. Tait attributed his improved mortality: (1) To the total abandonment of Mr. Spencer Wells's clamp; (2) to the thorough cleansing of the peritoneum, as recommended by Keith; (3) to the draining of the peritoneum, as recommended by Keith; (4) to increased personal experience; (5) to the diminished number of cases which had been previously tapped; the two of his patients who had died from thrombosis had been tapped, one sixteen and the other thirty times. He believed that if tapping was never adopted there would be no mortality after ovariectomy except from tetanus and similar outstanding risks; (6) the complete abandonment of antiseptic treatment; (7) the establishment of hospital discipline and hygiene; this he deemed of so much importance that in only exceptional circumstances would he consent to operate in private houses.—Dr. WARD COUSINS said that one danger of tapping was rotation of the pedicle on itself.—Mr. COATES (Salisbury) said that it was very difficult to harmonise Mr. Tait's statements with those of Dr. Stokes earlier in the day in reference to antiseptics. But his experience in general surgery was that while before his adoption of the Listerian treatment he did not obtain primary union of wounds in one per cent. of his cases, since that adoption he obtained it in every case. He incidentally mentioned a case of a very large splenic tumour, in which he was urgently requested to do, at any rate, an exploratory operation. On opening the belly and passing in his hand he found a large number of soft very vascular adhesions between the tumour and the abdominal wall, in tearing through which there was very free hæmorrhage; when this had ceased he closed the wound. The patient recovered, and from that time the tumour rapidly shrank in size.—Mr. M. THOMSON referred to the great diminution in the mortality of his cases that Mr. Tait observed when he first adopted the antiseptic treatment, and maintained that the results of general surgery abundantly proved the value of this treatment.—Dr. BANTOCK, in opposition to Mr. Tait, maintained that adhesions of ovarian tumours to intestine and pelvic organs are serious complications of ovariectomy. He had given up antiseptics, and he had not had more septicæmia than other operators who had used it, and he asserted that Listerism had not freed us from septicæmia.—Dr. SUTTON (Pittsburgh) had spent a considerable period in studying European surgery, and he stated that in Berlin, Vienna, Halle, Kiel, and Leipzig he found antiseptics everywhere, and such results obtained with it that on coming to England he dared not have opened the abdomen without employing antiseptics. He then went to see Keith's practice, and his views were changed; for Dr. Keith and his son (who has done five cases) had had a run of fifty-five cases of ovariectomy with only one death; alluding to Dr. Keith's abandonment of Listerism, he said that he had Dr. Keith's authority for stating that he had never used the carbolic spray stronger than was recommended by Prof. Lister. He had also seen Mr. Tait's practice for three or four weeks, and he had been very careful to watch his practice closely; but he had only seen one of his wounds in which there was a drop of pus—one already mentioned by Mr. Tait. In America antiseptic surgery had many friends in the East, but had not made much headway out West; and since the International Congress all American surgeons were waiting to see what the English surgeons would make of this question.—Dr. ED. TAYLOR, who was for some years Mr. Spence's assistant, said that the question

was one of careless surgery *versus* first-rate surgery. Listerism was but a cover for careless surgery, the results of which had been squallied by Mr. Spence's first-rate surgery. —Mr. TAIT, in reply, said that the unfair treatment he had received in London had reached such a point that he had had to threaten one gentleman with an action for libel. He advocated placing the operation of ovariectomy in the hands of a few surgeons only. In reference to the question of antiseptic surgery, he stated that he found one great argument against it in the constant changes which were being introduced into it. One preparation was always being abandoned in favour of another; the original catgut ligature was replaced by the chromic gut; and a new method of preparing the latter was recently introduced. If the practice were so perfect as had been represented, it would not need such constant modifications.

The last meeting of the section was mainly taken up with a discussion on bone-setting, which was opened by Mr. HOWARD MARSH, who referred to the cases benefited by "bone-setters," and urged that these should be taken in hand with more boldness by surgeons, while many cases of stiff joints should be prevented by more judicious treatment. —Mr. W. ADAMS followed with a paper on the same subject, in which he attempted to classify the cases which would be benefited by forcible movement; and he urged that the treatment should be gradual and prolonged, rather than rapid. —Mr. DAQUE FOX, who had assisted one of the family of Taylors, for many years "bone-setters," gave a very interesting account of the work of the firm. He said that in his experience "bone-setting" consisted largely in the treatment of recent fractures and sprains, and to only a limited extent in stiff joints. He urged surgeons to take more pains in the treatment of sprains, strains, and other apparently minor and simple injuries, which, if neglected, were often attended with grave inconveniences. —Mr. BERNARD ROTH related two cases of stiff shoulder after injury in which the treatment by forcible movement had not been successful, and he stated that the shoulder joint was not favourable for this treatment. —Mr. PEARCE GOULD, referring to cases in which the adhesions were mainly, if not entirely, extra articular, said that it was of importance to break down all the adhesions at once, and then to persevere with passive movement to the full extent, and gradually to bring up the nutrition of the wasted disused muscles by active movements; perseverance on the part of surgeon and patient was very necessary. —Mr. RICHARDSON CROSS gave the results of his experience at Bristol, which had been rather large. —There was not time to read all the papers set down, and one of the disappointed authors expressed himself as greatly aggrieved at this, and doubtless will not again offer a paper to the Association.

#### OPHTHALMOLOGY.

At the first session of the Section a discussion on the Extraction of Cataract in the Lens Capsule was opened by Dr. EDWYN ANDREW, who described new instruments to separate the lens in its capsule by tearing through the suspensory ligament. To obviate all pressure upon the globe during the operation he has discarded all forms of speculum, and instead he passes a thread of catgut through one or both eyelids, and by it has the lid or lids held apart and away from the globe. Dr. Andrew advocated a more frequent resort to this operation. The general opinion elicited was that this mode of cataract extraction is good in over-ripe cataract; and that it is easier to perform the older the patient, owing to the lessened resistance of the suspensory ligament in old age. In connexion with this latter point Mr. PRIESTLEY SMITH stated the interesting fact that having experimented on the extraction of the lens and capsule on the dead body in many cases, he had found it was much easier to do it in the corpses of aged persons. —Mr. C. MACNAMARA, whose name is associated with this operation, and who has had a large experience of it, stated that he prefers it to any other in properly selected cases, and particularly in old people.

Next day Mr. ANDERSON CRITCHETT read a paper on the Treatment of Lamellar Cataract, in which he advocated, in preference to removal of the lens, the formation of an artificial pupil by Tyrrell's hook.

Dr. ARTHUR BENSON followed with a paper on the Treatment of Partial Trichiasis. This is an affection which has hitherto been very troublesome, and the plan Mr. Benson recommends is to thrust one pole of an electrolytic machine into the eyelid, towards, or, if possible, into the erring

hair-follicle, and to place the other pole on the forehead. The object is to destroy the hair-follicle, and the treatment is continued until the eyelash comes out easily with the root-sheath attached.

Mr. NETTLESHIP and Mr. PRIESTLEY SMITH related three cases of Neuritic Atrophy of the Optic Nerve followed by continuous dropping of watery fluid from the nose. The fluid possessed negative characters, and was not cerebro-spinal. In one of the cases there was evidence of a growth in the nose, and in another the nasal mucous membrane was thickened and excoriated, but whether as the cause or the result of the discharge was not known. In one case there were also curious nervous symptoms, drowsiness and stupor, when the flow temporarily ceased; and during one of these attacks the patient died, but an autopsy was not obtained. Mr. PRIESTLEY SMITH showed at this meeting a new registering perimeter, which had the merits of simple construction and inexpensiveness.

Mr. NETTLESHIP opened a discussion on the value of eye symptoms in the Localisation of Brain Disease. The principal points alluded to were unioocular papillitis, with evidence of intracranial disease; optic atrophy, especially in relation to colour-blindness; hemianopia, and the recently recorded cases of hemiachromatopsia, the author thinking it probable that in most cases of hemianopia the lesion is higher up than the optic tract; cerebral amaurosis from lesion of the occipital lobes; ocular paralyses, peripheral, nuclear, and cortical. Attention was called to several other conditions bearing more or less closely on the subject—e.g., "pseudo-glioma," with brain symptoms, recoverable infantile amaurosis, hydrocephalic choroiditis, megrim, complicated herpes of cranial nerves, and others. —A short discussion followed, in which Dr. Edwyn Andrew, Dr. Hughlings Jackson, and Mr. Priestley Smith took part.

#### PATHOLOGY.

At the first meeting of this Section considerable inconvenience was occasioned by the failure to keep his engagement of Professor Hamilton, who had promised to open a discussion on the Pathology of Diabetes. —Dr. STEPHEN MACKENZIE was called upon, without notice, to take his place, and specially referred to the cause of death in diabetes, and the nature of diabetic coma, which he discussed, maintaining that it was complex, in the majority of cases being due to acetonaemia, and in only a small proportion of cases due to fat embolism. He agreed with others in believing this coma to be most common in young subjects. The statistics of the London Hospital were quoted to show the relative frequency of the various complications of diabetes. —Dr. PAVY enunciated his well-known views on Glycogenesis and Glycosuria. —Dr. SAUNDY stated that although he had carefully looked for it he had not often succeeded in demonstrating fat embolism in death from diabetic coma. —Dr. SHINGLETON SMITH contended for the nervous origin of diabetes; and as one piece of evidence, related a case of tumour in the cervical region of the spinal cord, which was accompanied with glycosuria. At the same meeting,

Dr. SAUNDY read a paper on the changes in the Sympathetic in Bright's Disease, and detailed observations of his own.

Dr. HUGHLINGS JACKSON read a paper by Dr. Gowers to accompany a demonstration of microscopical specimens of morbid changes of the spinal cord.

At the second meeting of the Section,

Mr. JONATHAN HUTCHINSON, in a speech considerably exceeding the recognised limit of time, opened a discussion on the etiology of tumours, in which he insisted on their local origin, and dwelt particularly upon rodent ulcer and the pre-cancerous stage of disease. —Sir JAMES PAGET followed, and quoting many cases illustrative of his views, contended for the dual origin of malignant tumours, constitutional tendency, and local change. —Mr. BUTLIN gave an excellent demonstration of the microscopical appearances of the chief forms of tumours. —Dr. THIN showed some hairs in which trichophyton tonsurans had been artificially cultivated; and Mr. ABRAHAM gave a very interesting demonstration of granulation tissue in a sponge network as obtained in the new process of sponge-grafting.

A paper on Sarcoma of the Bladder was read by Mr. R. WILLIAMS.

The closing meeting was opened by an exhaustive paper on Rodent Ulcer by Dr. SANGSTER, in which he clearly

established the fact that the disease is not primarily connected with the sweat-glands, but that the morbid change starts from the Malpighian layer and outer sheath of the hair-follicles.—Dr. THIN disputed this view. The rest of the morning was occupied with a demonstration of various forms of bacilli, which excited a good deal of interest, and was one of the most successful events of the meeting.—Dr. HERON showed Ehrlich's process of preparing tubercle bacillus, and he was followed by Dr. GIBBES, who demonstrated his process of preparing the same bacilli, which was described in THE LANCET of August 5th. It was very evident that this process, while decidedly simpler than Ehrlich's, was also more effective, and is, therefore, more useful.—Dr. S. MACKENZIE also showed a specimen of Tubercle Bacillus prepared by Goldammer's method.—Dr. SHINGLETON SMITH showed Bacillus Anthracis, and Dr. THIN the Bacillus of Leprosy.

## PUBLIC MEDICINE.

At the first meeting, Dr. SWETE, in an interesting paper, detailed the various sanitary improvements carried out at the Worcester Infirmary since its foundation, and in this way gave a sanitary sketch of the advance of sanitary science during that period.

The two chief discussions were on the Notification of Infectious Disease, which was further debated at a general meeting, as reported above; and on the Public Medicine aspects of the Alcohol Question, which was introduced by Dr. NORMAN KERR, who said that some diseases were caused by alcohol alone, as delirium tremens, dipsomania, and alcohol poisoning, acute and chronic. Some, which arose from other causes, sometimes were caused by alcohol directly, as alcoholic phthisis, gout, and paraplegia. Alcohol might also be a main contributory factor, as in fatal frostbite and sunstroke after drinking. The proportion of sickness and death from alcohol had been shown in the Government returns of the Indian Army for 1849. The mortality of the temperate was double, and that of the intemperate quadruple that of the total abstainers. The abstaining deaths were 11.1 per 1000; the temperate 23.1; and the intemperate 44.5. The admissions of the abstainers were only 10.7 per 1000 less than those of the temperate, showing that the diseases of the former took a milder form. This experience was confirmed by a recent actuarial report, comparing the sickness of the Sons of Temperance with three groups of non-abstaining friendly societies. The average sickness per annum of the temperance "Sons" was 7.48 weeks; of the Oddfellows (City) 26.20; (Rural) 24.68; and of the Foresters 27.66. Insurance companies were so satisfied of the superior healthfulness of the abstinent, that one had paid the abstainers insured 23 per cent. additional bonus, and another offered an extra bonus of 20 per cent. The United Kingdom Association showed a 17 per cent. lower death-rate in the abstaining than in the general section. In Glasgow there had been a sudden increase of nearly 1000 deaths in the year that the lowering of the spirit duties began to operate. The influence of alcohol on the death-rate was well illustrated in the following table from the Registrar-General's report for 1880:—

Mean Annual Rate of Mortality in England for Three Quinquennads.

Classes.	Cause of Disease.	Annual Deaths to 1,000,000 Living.		
		Five years, 1865-9.	Five years, 1870-4.	Five years, 1875-9.
I.	Zymotic Diseases	5171.8	4842.0	3887.6
II.	Constitutional	4145.4	3771.8	3631.0
III.	Local	8887.2	9151.0	9345.0
IV.	Developmental	2605.0	3362.2	3037.0
V.	Violent Deaths	797.4	750.4	744.0

From this table it would be seen that in every class except one the mortality had steadily diminished; but in Class III. the mortality had as steadily increased. In this class the principal increase had been in deaths from diseases of the brain and nervous system, of the organs of circulation, of the respiratory organs, of the liver, and of the kidneys. These were precisely the organs most apt to be seriously affected by indulgence in alcohol. Dr. Kerr had estimated the annual deaths from personal intemperance in the United Kingdom

at 40,500. Dr. Morton's estimate was equivalent to 14,000 more. The Harveian Society's first inquiry showed results equal to 2300 more deaths for England and Wales than Dr. Kerr had attributed to the whole kingdom. Their second inquiry would give nearly 10,000 more than his own computation. Dr. Richardson put the figures at 50,000. The indirect fatality by violence, disease, poverty, &c., arising from the intemperance of others was probably double the mortality of the personally intemperate. Dr. Noble's and Dr. Richardson's ascription of one-third of the total deaths would amount to 235,775 deaths from alcohol in 1880, far beyond Dr. Kerr's estimate of 120,000 in all. The association ought to ask returns from 500 practitioners in different parts of the kingdom, to afford a fair basis for an accurate estimate. The amount of alcohol ordered to the poor ranged from none at all up to £4 6s. 5d. per pauper. There had been a great reduction recently. In Greenwich and Whitechapel this had been two-thirds of the alcoholic expenditure, in Shoreditch one-half, and in Wandsworth and Clapham nine-tenths. At St. George's the charge for alcohol had fallen from £1500 per annum to £13. In St. Marylebone, in 1881, the cost was £1633 in the workhouse. During the three quarters already expired of 1882, the cost in the workhouse was nil, and in the new infirmary £280. This showed a reduction of £1300 per annum. The health of the inmates had not suffered, while their good conduct had improved. The Habitual Drunkards Act was very imperfect—the applicant for admission to a retreat having to confess himself an habitual drunkard before two magistrates; but it was desirable to give it a fair trial. It was hoped to open the Dalrymple Home for Inebriates this year, and financial support was much needed. For the cure of dipsomania, total abstinence was indispensable. Heredity was the chief predisposing cause. The marked increase in the variety and consumption of unwholesome beverages was an aspect of the question which called for the consideration of students of public health, as an increased use of non-intoxicants was a favourable omen of the future improved sobriety and consequent health of the community.

The second meeting was devoted to a lively discussion on the compulsory notification of infectious diseases. Dr. RANSOME led off with a paper on the Scientific and Practical Objects of Registration of Disease, in which he strongly advocated compulsory notification.—Dr. CARTER, of Liverpool, as strongly opposed this, and he urged that it was necessary for those towns which had adopted it to show a greater diminution of zymotic diseases than occurred in other towns which could not otherwise be accounted for. Such proof, he alleged, had not been given; for instance, Bolton, which had such an Act in force, had not progressed so fast as Liverpool, which was without the Act, or the country generally. The Act led to concealment of disease, as he showed by ascertained cases. He feared, too, that the demands made in the name of science would be greatly increased, and this, putting compulsion on medical men, compulsory removal to hospital, and compulsory closure of shops and schools would soon be followed by still more arbitrary requests. The discussion was finally transferred to the ensuing general meeting, as reported elsewhere.

## OBSTETRIC MEDICINE.

The President, Dr. Leishman, was unable to attend, and the chair was taken by Dr. COGHILL, who made a few introductory remarks.

Dr. BANTOCK read a paper on his cases of Hysterectomy, and in the subsequent discussion Drs. J. Williams and Wallace strongly deprecated a frequent resort to this operation, asserting that the cases justifying it were not numerous.

Dr. EDIS gave a *précis* of the rational treatment of Menorrhagia, and Dr. C. H. ROUTH described a form of Dysmenorrhœa associated with Gonorrhœa.

The second meeting was entirely taken up by a discussion on Subinvolution of the Uterus, its causes, its relation to uterine disease, and its preventive treatment, which was opened by a paper by Dr. JOHN WILLIAMS. He referred to the various methods for determining the progress of the involution of the uterus after delivery and to the work of Heschl, Dupaul, Serdukoff, Milsom, and Sinclair. The uterus disappeared into the pelvis on or before the twelfth day after delivery, when involution goes on healthily. Taking this as a standard, Dr. Williams found, from the study of 113 cases, that the causes of involution are post-partum hæmorrhage, retention of portions of placenta or membranes, lacerations of the perineum, pelvic inflammations and fever during the lying-in

period. Lacerations of the cervix do not appear to give rise to it. Subinvolution causes menorrhagia, dysmenorrhœa, and prolapsus. The pelvic inflammations so frequently associated with it are not its results. Its preventive treatment consists in completely emptying the uterus after delivery, maintaining an efficient contraction of the organ, and preventing fever. The best means of securing the two last are the frequent use of hot disinfecting vaginal injections, and perfect closure of tears of the vaginal orifice.

### MEETING OF FELLOWS OF THE COLLEGE OF SURGEONS AT WORCESTER.

A MEETING of Fellows of the Royal College of Surgeons of England, called by advertisement, was held at the Medical Library, Worcester, on Thursday, August 10th, President C. G. Wheelhouse, Leeds, in the chair. There were present: Mr. William Adams, London; Mr. Allard, Tewkesbury; Mr. J. Archer, Birmingham; Mr. Banks, Liverpool; Mr. Balding, Royston; Mr. Carter, Pewsey; Mr. Cowell, London; Mr. Crosse, Norwich; Mr. Cornwall, Fairford; Mr. Pearce Gould, London; Mr. Harris, Redruth; Mr. Reginald Harrison, Liverpool; Mr. Hacham, Birmingham; Mr. Husband, Bournemouth; Dr. Howard, London; Sir William MacCormac, London; Mr. Manby, Wolverhampton; Mr. Rushton Parker, Liverpool; Mr. Augustin Prichard, Clifton; Mr. Oliver Pemberton, Birmingham; Mr. Solomon, Birmingham; Mr. Lawson Tait, Birmingham; Mr. Teale, Leeds; Dr. Rayner, Stockport; Mr. W. L. Underhill, Tipton; Mr. Welch, Honiton; Mr. Watkin Williams, Birmingham; Dr. Roger Williams, London; and Mr. Bartleet, Birmingham. Mr. Bartleet said he had received numerous letters approving of the meeting at Worcester, and expressions of regret at inability to attend from Mr. Macnamara, London, and Mr. Pilcher, Boston. Mr. Wheelhouse and Mr. Bartleet having explained the objects of the meeting, it was proposed by Mr. Lawson Tait, seconded by Mr. Oliver Pemberton, and after considerable discussion resolved *nem. con.*, "That an Association of Fellows of the Royal College of Surgeons of England be and hereby is formed." "That the objects of this Association be the consideration of all matters affecting the interests of the Fellows and the government of the College." "That the Annual Meeting of this Association be held at, and during, the annual meeting of the British Medical Association." "That the Fellows attending the present meeting do form a Committee of this Association for the present year, and that Mr. Wheelhouse be President, Mr. Husband Treasurer, and Mr. Pearce Gould and Mr. Bartleet Secretaries, and that all Fellows of the College be eligible as members upon payment of an annual subscription of five shillings."

### POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

THE annual meeting of the Poor-law Medical Association was held at Worcester on the 9th inst. Dr. Joseph Rogers of London (President of the Council) presided, and observed that within the last two years, in consequence of certain occurrences, he had made up his mind to abandon as far as he was individually concerned the idea of appealing to the Local Government Board, and had determined to endeavour to mould their Association into a mutual defence association. As the result of his experience he was inclined to say that a most unkind feeling existed throughout the country between boards of guardians and their medical officers. He believed it arose from the circumstance that the pauper poor were looked upon as a horrible incubus by boards of guardians, and therefore anybody who had anything to do with them was tarred with the same brush.

The hon. secretary (Mr. Wickham Barnes) read the financial report for the year, and stated that there was a small balance in hand.

A general discussion then took place, in which various grievances of Poor-law medical officers were referred to, and the best method of their remuneration was canvassed. The

necessity for greater liberality on the part of the class of officers for whom the Association was established was also insisted on.

### ENDEMIC HÆMATURIA IN EGYPT.

To the Editor of THE LANCET.

SIR,—The circumstance that *The Times'* correspondent at Alexandria has telegraphed words of warning and alarm must be my apology for reopening this important subject.

The observations made public on the authority of Dr. Mackie seem to state the case very fairly, and professional readers of the telegram will have at once concluded that the "parasite" causing the disease was none other than the now well-known Bilharzia hæmatobia. As probably no European doctor has seen more cases of this kind than Dr. Mackie, the remarks are valuable, but perhaps it will be useful to supplement them.

When the Eastern Telegraph Company ascertained that their officers were suffering from the bilharzia disorder they acted with great promptness, and at their request I drew up a memorandum recommending certain prophylactic measures. This was printed and issued to the company's stations and employés. Guided by my advice the Board of Management allowed all their clerks to return home, placing six of these gentlemen under my professional care. It may serve to abate alarm when I state that none of the patients had the disorder in its severest form, and were it not that the symptoms had been aggravated by repeated attacks of intermittent fever, the general health of the victims would not have seriously suffered. Without doubt Dr. Mackie has good reasons for authorising *The Times'* correspondent to say that the disease is "often fatal," but so far as my observation extends the prognosis is generally favourable in uncomplicated cases if the patients are removed from the locality of infection. The exceptional instances are those in which there is an unusual degree of infection. In such cases even the strongest patient must sooner or later succumb to anæmia and its consequences.

Into clinical details one cannot now enter, but my meaning will perhaps be better understood if I place what may be respectively called "slight" and "excessive" invasions in contrast. In cases of the former kind not more than a dozen or so of the parasite's eggs will be passed at each act of micturition, whereas in the latter it is not uncommon for the patient to pass fifty, or, for that matter, a hundred dozen bilharzia eggs at a time. In severe cases the daily average of evacuated ova greatly exceeds this estimate. As before hinted, however, the severity of the symptoms and consequent dangers are, as a rule, more dependent upon associated disorders than upon the actual number of parasites present.

The natural history bearings of the bilharzia endemic are of great interest, especially in relation to sanitation and epidemiology. As, however, I hope to be able to draw attention to this part of the subject at the forthcoming Southampton meeting of the British Association, I will only add that what little was advanced on this score in the telegram of last week is in perfect accord with the results of recent scientific inquiry.—I am, Sir, yours truly,

T. SPENCER COBBOLD, M.D., F.R.S.

Portsmouth-road, August 14th, 1882.

PRESENTATIONS.—Last week a silver epergne and two silver candelabra to match were presented to Mr. John Bowes, of Richmond, Yorks, in recognition of the value of his professional services rendered to the town during a residence of fifty years.—On the 11th inst. a meeting was held at the National Schools, Seaforth, to bid farewell to Dr. Swaby Smith, who, after fifteen years' residence in the town, was about to remove to the West-end of London. An illuminated address was on the occasion presented to Dr. and Mrs. Smith, accompanied with a purse containing a hundred guineas, subscribed for by the members of St. Thomas's Church.

MR. R. CLAYTON MERCER, late of Accrington, has bequeathed £1000 to the Victoria University, Manchester, for the foundation of a scholarship in chemistry; £500 to the Manchester Royal Infirmary; £500 to the Manchester Eye Hospital, and £500 to the Blackburn and East Lancashire Infirmary.

# THE LANCET.

LONDON: SATURDAY, AUGUST 19, 1882.

THE position of a jubilee orator is not an easy one to fill. He is expected to survey the progress of things from the standpoint at which he has arrived, and to embrace the past, the present, and the future within his view. Of course this expectation relieves him of the trouble of seeking for a subject on which to discourse, with the uncertainty whether such subject is after all the most suitable for the occasion; but then, on the other hand, he may find, if he has to deal with such rapidly growing subjects as medicine and surgery, that the material at his command is far too abundant to be satisfactorily utilised or rendered palatable to his hearers. It was, then, doubtless with a sense of relief that the members of the British Medical Association listened to the orators of last week, and found that, although they had recognised what was required of them, they had resolved to attempt no comprehensive survey, but to deal rather with the leading principles and the directions in which their sciences are moving. This was pre-eminently the case with the orator in Medicine, Dr. WADE, who, in a sober and thoughtful address not marked by the impassioned eloquence of his surgical colleague, advocated the claims of rationalism in therapeutics as the aim of modern medical endeavour. Naturally his thoughts turned back across the half-century which had passed by since the medical men of England under CHARLES HASTINGS formed themselves into an association, and his comparison between the state of medicine then and now—a contrast which Dr. STRANGE had so admirably depicted the day before—centred in one great prophylactic and therapeutic measure, which had then nearly reached the limit of its popularity after an undivided sway for centuries over the medical mind. To those who have been educated in these latter days, the attempt to realise the extent to which this practice was carried in their fathers' times is almost impossible. The steps that led to this great revolution—the almost entire abandonment within a few years of a routine measure, in the efficacy of which there had been previously such abounding faith—were well described by Dr. WADE. It was a time of general upheaval, political, social, and indeed scientific; for science was then beginning to assert herself and to disturb settled dogmas of all kinds. No wonder that the dogma of the efficacy of bloodletting fell before the assaults made upon it by the scientific mind of MARSHALL HALL, supported as his arguments were by a body of facts obtained by experiment. Along with this questioning of authority there arose a new faith, which some would strangely miscall scepticism—faith in the powers of nature to restore the deranged mechanism to its integrity with or without assistance. The truth is that as our conceptions of the nature of disease widen, so necessarily must our belief in the recuperative power of nature expand; and the line in which therapeutics has to run is not in thwarting this natural tendency, or in lowering vitality by depletion and purgation, but in sup-

plying where indicated such reinforcement to the natural processes as may hasten the process of recovery, in removing the obstacles from the way, and in withholding the administration of that which may injure or retard the restoration. Those who think that by so doing medicine is falling from her high estate are but shallow-minded people after all—who imagine that vigorous and violent measures are the test of wealth of resource and of skill in treatment, and who would rather a dying man were tormented with all the drugs of the Pharmacopœia than that his path should be eased in its inevitably downward course. With the fall of bloodletting passed away other measures of so-called heroic therapeutics, and we look forward to the time when, with fuller knowledge of the action of remedies as well as of the natural processes of disease, medicine may become more and more entitled to take rank as a strictly defined science.

Whether this desirable state of things will receive speedy realisation may well be doubted. Errors there will be, many (like those instanced by Dr. WADE of the treatment of delirium tremens by digitalis, and of acute inflammatory diseases by alcohol) based on false generalisation, whereby systems of treatment are blindly perpetuated, and specifics vaunted on insufficient evidence. For with increasing knowledge comes the clearer revelation of the complexity of conditions that combine to make disease what it is, and yet it is so difficult to detach oneself from preconceived notions in its treatment. In one direction, at the present day, Dr. WADE thinks we are going astray; we are aiming too much at giving nutriment to an enfeebled frame, and too little at attempting the restoration of deranged function. This may be so; but how difficult it is for us, if we wish to walk by sight and not by faith alone, to continue to employ remedies the precise action of which, on general grounds, is often problematical, and as regards the patient is certainly so; bound down to certain rules of dosage and the like, and ignorant of a large part of the functional disturbances we are seeking to get right. Although, then, the scientific practitioner may be alive to the importance of pursuing rational therapeutics, although he may be persuaded that physiologically such or such a line of treatment is the most correct, yet is he constrained by certain arbitrary rules of his art, by certain generalisations framed by others, to adopt measures which may be not only unsound physiologically, but even harmful to the individual patient. What need for surprise, then, if he prefer to stay his hand, and, under judicious watchfulness, leave the cure in the hands of nature, bringing to her assistance, when necessary, such aids as seem most suitable. Medicine must make progress, but it must advance slowly in the direction of treatment if that treatment is to be based on the only sound foundation, that of the physiology of disease, or, in other words, of *pathology* in its broadest signification.

THE event of greatest interest to the surgeons assembled at Worcester was undeniably Professor STOKES's Address. The occasion—the jubilee of the Association,—the honoured name inherited and the high reputation borne by the orator, demanded a contribution to surgical literature of more than passing value. In substance, in form, and in delivery, the Address was fully equal to all expectations and hopes, and to his character as a skilful and wise surgeon Professor

STOKES has now added the reputation of an orator worthy of his country. We do not here purpose to follow him in all the points of his excellent Address. We concur fully in his choice of the three greatest advances in surgery during the last half-century so far as anæsthesia and the antiseptic treatment are concerned, and we well appreciate the reasons which led him to place osteogenesis as the third. We would, in passing, commend the scientific candour with which he admitted the claim of America to the introduction of anæsthesia into surgical practice, and the eloquent appeal for greater freedom in physiological investigation which naturally sprang from his sketch of the introduction of osteoplastic surgery, for the establishment of which experiments on living animals have proved so useful. The chief burden of the Address was the value of aseptic surgery, and none who heard it could fail to have been impressed, not only with the orator's knowledge of the facts, his thorough conviction of the soundness of the practice he advocated, and the eloquence with which he pleaded, but also, and perhaps even chiefly, with the earnest tone which ran through his whole appeal. He spoke as one to whom this was more than any mere scientific theory or discovery, or the doctrine of any school—as one who felt that it was a matter of stern duty and heavy responsibility, who felt that it was time that all personal predilections and personal pride should be put away in face of the ever-accumulating facts. It was a remarkable criticism on this Address that but a few hours later surgeons were attributing their success in abdominal surgery partly to the abandonment of all antiseptic measures, and were speaking of it as a cloak of careless surgery. Such discrepancies must arrest the attention of all intelligent observers; and assuming, as we are bound to do, that the facts stated are accurate, we must look for the explanation of the discrepancy in the mode of statement or in the deductions drawn therefrom. The position taken up by Mr. LAWSON TAIT is certainly an extreme one. He states that his latest brilliant results in ovariectomy are partly attributable to his discontinuing to use any so-called antiseptic measures. Although he at first thought that the adoption of LISTER'S treatment had greatly lessened his mortality after this operation, he now teaches that in this he was deceived, and that the improved results were due to other modifications he introduced into his practice at the same time. It is not any change of opinion, however, that we would now discuss, but rather the facts alleged. We do not know what views Mr. LAWSON TAIT may hold as to the origin of septic diseases; for ourselves, we are content to accept the "germ theory," as it is now generally called. On the one hand, then, we have Professor LISTER, Professor STOKES, VOLKMANN, NUSSBAUM, ESMARCH, and a whole array of other surgeons, asserting that just in proportion as they have employed efficient means of preventing the access and development of "germs" in wounds and discharges, have they been able to banish entirely all forms of septic disease from their practice, even under conditions in which such diseases have before been rampant. On the other hand, we have Mr. LAWSON TAIT recommending the entire abandonment of all antiseptic precautions. But he comes altogether too late to succeed in controverting Mr. LISTER'S doctrine and practice. The history of surgery shows conclusively that

wounds treated without regard to asepsis are liable to putrefactive changes and septic complications. No amount of statistics such as Mr. TAIT adduces can prove the negative. Their sole value is to show that in that particular operation asepsis is secured by other means than antiseptic dressings. Nothing can ever upset the established fact that the antiseptic treatment of Mr. LISTER, where thoroughly carried out, has reduced the mortality from septic diseases in a far greater degree than any or even all other improvements in wound dressing that have ever been introduced. When facts at first sight at variance with these are observed, the scientific course is to see in what way they can be reconciled with them, and not to concentrate attention on them, and refusing to look beyond them, affirm that in them alone, and in one interpretation of them, lies "the truth, the whole truth, and nothing but the truth." Mr. TAIT'S facts support Mr. LISTER'S views rather than contradict them. He is an experienced and skilful operator who leaves the parts in the best condition for healing, and disturbs them as little as possible. When the wound is entirely closed, the conditions for primary healing are satisfactorily secured, the cut surfaces are maintained in exact apposition, no tension exists, there are no foreign bodies in the wound, and on the inner surface is a membrane in which plastic exudation occurs with remarkable rapidity. The wounded parts in the cavity within are then shut off from all outside contamination, tension from retained fluid does not occur, absorption rapidly ensues, and even if "germs" have been admitted during the operation, they do not find a suitable nidus for development if the fluid does not accumulate. In the cases that are drained, on the other hand, the fluid is allowed to escape as fast as it is secreted, there is never any cavity nor retained fluid, and thus again asepsis is secured. The real reading of Mr. TAIT'S figures would therefore seem to be that he has learnt from experience exactly when it is necessary to use a drainage-tube, and thus avoids all retention of peritoneal secretion, and all probability, or even possibility, of septic decomposition within the abdomen. It is therefore quite unscientific to suppose that Mr. TAIT'S experience can be used as an argument against the aseptic treatment. One of Mr. TAIT'S attacks upon Mr. LISTER'S teaching was singularly unhappy. He urged that the frequent changes in and additions to the aseptic treatment afforded a strong argument against its value. This development of the practice is, on the other hand, one of the surest signs of its vitality and truth. Mr. LISTER has never wavered from his original assertion of the principle of his treatment, and just as soon as he announces finality in his practice will he forfeit his claim to the character of a scientific surgeon. To improve methods is not to change a principle. Because a ligature acknowledged to be imperfect has been replaced by a better one, it in no way follows that the principle of using an absorbable animal material has been found faulty. In a word, then, antiseptic surgery showed no signs of waning vigour at the Worcester meeting, and nothing that was stated there need in any way disconcert any follower of Mr. LISTER.

We have not sufficient space to refer to the other topics of interest that were raised. The surgery of arteries proved an attractive subject of debate, and evidently we are far

from finality in this direction. The most important communication on this head was undoubtedly Mr. THOMSON'S case of ligation of the innominate artery, which though unfortunately not successful, will accomplish a useful purpose if it brings the conviction that this operation is not beyond the pale of surgery. The discussion on bone-setting shows that the younger generation of surgeons are more alive than their seniors to their responsibilities in this direction. The subject is worthy of more study than it has generally received, and we hope that Mr. DACRE FOX'S appeal will be responded to. Mr. GREIG SMITH suggests that operative interference in diseases of joints should be pushed even beyond its present limits. In all directions the outlook of surgery as presented at Worcester is encouraging; there are signs of advance all along the line, and of men rising up to take the places of those to whom surgery owes so much of its progress during the last five decades.

A GOOD *résumé* of the opinions at present held in regard to colour is given by M. J. SOURY, in the *Revue des Cours Scientifiques*. The theory, which may now be called old, though it replaced that of NEWTON, is the YOUNG-HELMHOLTZ theory. According to this, the retina of man possesses three distinct kinds of nerve fibrils, each of which is capable of distinguishing one of three colours supposed to be fundamental or elementary. One of these sets of fibres is sensible to red alone, another to green, and the third to violet or perhaps to blue. Our entire chromatic scale is made up of combinations of these three primary colours. Every sensation is due to the excitation of the fibres of the retina by these tints, each set of fibres being strongly stimulated by its own special excitant, and feebly stimulated by the others. In the case of red, for example, the terminal apparatus of the fibres adapted for conducting red are powerfully stimulated by the large waves of the less refrangible extremity of the spectrum, whilst the terminal apparatus of the nerves adapted for green and violet are very feebly stimulated, and the sensation of red is the result. In like manner, when the sensation of green is perceived, the terminal apparatus of the nerves adapted for conducting the impression of green are stimulated by the waves of moderate amplitude in the middle of the spectrum, whilst the red and violet fibres respond but slightly to such waves, and the sensation of green results. And so, too, the fibres adapted for conducting violet respond to the short and rapid waves of the more refrangible rays which have only moderate action on the green and still less on the red conducting fibres. The intermediate colours, such as orange, are due to the simultaneous stimulation of the several sets of fibres to a greater or less extent, and when all these sets are equally excited, the impression of white light results.

Lately, a new theory—that of HERING—has been advanced. According to this physicist there are six simple sensations of vision, and the various colours seen result from their different association and blending. These elementary sensations are disposed in couples or antagonistic pairs: black and white, green and red, yellow and blue. On this theory violet is a compound colour formed by the blending of blue and red, and in an ordinary perception of colour four primary sensations are excited: black and white

and two colours; but the blue and the yellow are never simultaneously excited, nor are the red and the green. When the blue sensation is experienced the yellow is virtual, and, though present, is not perceived by the mind. Black and white are capable of mingling, and produce all the shades of grey, but red and green or blue and yellow have no disposition to blend, but rather behave like the poles of an electric battery, and it is in this sense that the school of HERING, of which HAPPE is the chief exponent, speak of the polarity of colours. The organic substratum of colour sensation, according to HERING, is not the terminal apparatus of the nerve fibre itself, but certain hypothetical substances, such as the visual purple, which undergo chemical change. On looking at "white" light, the visual purple, by a photo-chemical process, is constantly undergoing decomposition and destruction, and is as rapidly restored. Red light decomposes the visual purple slowly, violet light decomposes it more rapidly. Further, on HERING'S theory, processes both of disassimilation and of assimilation are supposed to take place, so that when exposure to red light has exhausted or partially destroyed the visual purple, or its mother substance, purpurogene, green light aids in the reparation of this material, and fits the eye again for perceiving red light. Black does the same office for a retina exhausted with white light, and blue for yellow. This theory affords a good explanation of the phenomena of contrast, and of complementary colours. A red wafer placed on a sheet of white paper gives the sensation of a vivid red disc. As long as it is looked at it causes disassimilation of the retinal purple, which is as constantly renewed; but if the eyes be closed, the sensation of red vanishes, and is replaced by green. Why? Because assimilation is now taking place in excess of disassimilation. When one of these states is equal to the other two, the two antagonistic sensations are reciprocally destructive. Hence red and green do not blend to form white. The third theory, originally suggested by DRAPER, and more recently developed by PREYER and by CHARPENTIER, refers the colour sensations we perceive to modifications of temperature. PREYER distinguishes the quantity or intensity, the quality or tone, and the temperature. The intensity depends on the force with which the retina is impressed by the ethereal waves; the quality on the nature of the excitation caused by the vibrations of the particles of ether constituting the waves; vibrations the rapidity of which increases with the diminution in the size of the waves. In regard to temperature, PREYER differentiates the colours into hot and cold—the warm colours are red, orange, yellow, and yellow-green; the cool colours are green-blue, blue, and violet. CHARPENTIER, who has just completed a series of researches with LANDOLT, finds that the statements recently made to the effect that certain zones of the retina are specially adapted for the perception of certain colours have been founded on imperfect observations, and that even the most peripheral portions of the retina can differentiate colours providing they are sufficiently intense. Aware of the observations of MUNK and SAMELSOHN, the former of whom seems to have demonstrated that the seat of chromatic sensation is in the cortical layers of the occipital lobes, whilst the latter has published a case of hemianopsia, in which the sense of

space was preserved in the affected half of the retina while the chromatic sense was lost, CHARPENTIER differentiates in every normal eye a sensibility for light, a sensibility for colour, and a visual sensibility or sensibility for form. In every chromatic impression made on the peripheric regions of the retina he further distinguishes three phases: a simple impression of light, a vague indeterminate impression of colour, and a distinct impression of the true colour. The first phase he thinks clearly proves that the luminous sensation is distinct from that of colour, that it is the result of a simple excitation of the optic nerve, but in the second phase the cerebral centres for colour are excited, and the reason that a quicker and surer recognition of colour is made by the macula and central parts of the retina is only because they are more used. The sense of colour and of light being a general function of the retina, he regards neither the rods nor the cones as the retinal elements which are stimulated by chromatic stimuli. He rather looks to the layer of ganglionic cells which lie on the anterior part of the retina as the functionally active elements. It is clear that there is still a wide field for research in this subject open to the scientific explorer.

THE Report of the Select Committee of the House of Commons upon the administration, operation, and effect of the Contagious Diseases Acts of 1866 and 1869 has just been published. The Committee was first appointed in June, 1879, and was continued by four subsequent reappointments, so that the inquiry has extended over a period of upwards of three years. The subject was divided by the Committee into two branches: first, the hygienic effects of the Acts; and, secondly, the constitutional, moral, and social aspects of their principles and administration. And this division has been followed in the Report, prefaced by a summary of the provisions of the Contagious Diseases Acts, and a statement of the recommendations of the Royal Commission of 1871.

Under the first head—the hygienic effects of the Acts—a very careful analysis is given of the statistics obtained from the Army returns, a comparison of the results as to disease at the military stations subjected to the Acts and those unsubjected to them, and an investigation into the extent of the fluctuations in the proportion of cases occurring in the two groups respectively during periods prior and subsequent to the introduction of the Acts. The Committee also had under consideration an objection which has been often raised to the Army statistics, that under the head of “primary venereal sores” are included two different forms of the disease—the hard, or, as it is termed by some, the “infecting” sore, and the soft or “pseudo-syphilitic.” They came to the conclusion that this was unavoidable, and did not appear “to interfere with the value of the departmental statistics of the disease.” It would be impossible, in the space at our disposal, to enter upon the details of this portion of the Report, but we recommend the study of them to all who take an interest in the question. The conclusion at which the Committee arrived as regards the effects of the Acts on the efficiency of the Army is, that “out of 16·69 per 1000 who would probably have been withdrawn from the efficient strength of the Army in the subjected districts, if they had

not been under the Acts, 5·38 per 1000 have been daily saved to the efficient strength of the army by the operation of the Acts. To this saving ought to be added the gain to the service derived from the increased immunity of the men from the various debilitating and incapacitating disorders which, though not classed as venereal diseases, not unfrequently result therefrom.” The Committee also report as their opinion that the Acts have had a beneficial effect in reducing the amount of venereal disease among the civil population, and in diminishing the virulence of the disease among the prostitutes in the subjected districts. They conclude by saying that the “extent to which the Acts have diminished primary and constitutional syphilis in the subjected districts appears of itself to your Committee to establish the hygienic utility of the Acts. The diminution of gonorrhoea in the subjected districts, attributable to the Acts, in the same period is less considerable, but substantial.”

Under the second head of the inquiry—the constitutional, moral, and social aspects of the principles and administration of the Acts—the Committee carefully considered the objections raised against them by the opponents, and the advantages (other than hygienic) claimed for them by the advocates, of the Acts. The conclusion at which they arrived was that the objections were not sustained by the evidence adduced in support of them. One of these appeared to the Committee so serious, that if it could be proved, it would be fatal to the maintenance of the Acts: “that virtuous women may be, and are, brought under their operation.” They therefore spared no labour in probing it to the utmost, with the result that “the charges of misconduct brought against the police have broken down, and they desire to record their concurrence in the opinion expressed by the Royal Commission, ‘that the police are not chargeable with any abuse of their authority, and that they have hitherto discharged a novel and difficult duty with moderation and caution.’” The Committee consider that the Acts are shown to have been beneficial by the diminution of prostitution in the subjected districts, and especially the diminution of juvenile prostitution, by the improvement of the physical condition of the women, and by the promotion of public order and decency in the subjected districts.

After this protracted, careful, and patient inquiry, the Committee came to the conclusion that they could not recommend the repeal of the Acts. They state very forcibly that the repeal in districts where they have been in operation for thirteen years and more would mean: “a. Full licence for venereal disease of all kinds to disseminate itself unchecked either by police or by hospital treatment. b. A serious diminution in the effective strength of our army and navy, which would be especially felt in the event of their services being suddenly called into requisition. c. The relegation of numbers of these unhappy women to the state of hopeless misery, squalor, and disease in which they lived before the system was introduced. d. The letting loose of increased crowds of abandoned women and girls of all ages upon streets and thoroughfares swarming with soldiers and sailors, with little or no practical check or control over their behaviour. It is scarcely surprising that such a prospect should excite feelings of dismay in the

minds of the more intelligent and thoughtful inhabitants of subjected districts."

The Committee do not recommend the extension of the Acts to the United Kingdom generally, apparently from a feeling of deference to the opinions of a considerable minority opposed to it; in other words, because public opinion is not yet ripe for such an extension. But they are decidedly of opinion that "it would be unfair to soldiers and sailors, and unwise from the point of view of the efficiency of the service, to abolish a system which, in localities favourable to its maintenance, has been found effective for rescuing men of both services from diseases to which they are especially exposed." They do not recommend any alteration in the registration and police supervision, the periodical examination of the prostitutes, or the detention in hospital of those who are diseased. They recommend that in some of the unsubjected districts female lock hospitals should be established; additional powers be given to the police to enter houses of ill-fame for the purpose of taking steps to diminish prostitution; and also powers to institute proceedings for the prosecution of brothel-keepers; that it should be a misdemeanour for any person to receive into a house any girl under sixteen years of age for an immoral purpose; and that police magistrates should have power to grant a search warrant in cases where there is good reason to believe this has been done, and to commit for trial any person committing such an offence.

The evidence taken before the Committee, and on which the Report is founded, will be published in due course, and will no doubt bear out their recommendations. In the meantime we can only say that the Report itself affords sufficient proof of the care with which the inquiry has been conducted, and the impartial consideration which has been given to the various important points involved in the question under investigation. The conclusion at which the Committee have arrived, in favour of the maintenance of the Contagious Diseases Acts, must commend itself to every one who has any knowledge of the widespread prevalence of venereal disease in our garrison towns and sea-ports, and of its injurious effects upon the health of the population.

MODERN pathology has proved beyond question that oxidation processes in the body are increased during pyrexia. The increase in the most important product of oxidation, carbonic acid, has long been known; but the corresponding increase in the amount of oxygen taken in has only lately been proved by LILIENFELD and PINKLER. Further steps in the investigation are necessary to determine the organ in which the increased process of combustion occurs, and the manner in which it takes place. Hitherto, on these subjects, we have only more or less probable hypotheses. According to a recent statement by Professor ZUNTZ, of Berlin, the facts known are susceptible of two explanations. The increased metabolism of pyrexia may occur in consequence of the presence of a ferment-like substance in the blood, which causes a destruction of the elements of the blood and tissues. So far as micro-organisms have been discovered to be the pathological cause of many fevers, the interchange of material involved in the growth and multiplication of these parasites may be the source of the increased interchange of material in these diseases. The

second hypothesis is that the interchange of material is conditioned through the nervous apparatus, on which the pyrogenic irritant exerts its primary action, and through which the interchange of material is increased in one or in many organs. Since the chief part of the oxygen comes from the muscles, and the amount of oxidation is certainly determined in them by nervous influences, the question arises, in connexion with this second hypothesis, whether an increased innervation of the voluntary muscles is not the cause, alone or combined with other influences, of the increased metabolism of fever. The explanation derives support from the rigor at the commencement, and the strong sense of muscular fatigue which attends the entire course of fever.

To obtain further evidence on the question, and so to endeavour to decide between the two above-named hypotheses, it appeared desirable to cut off the influence of the nervous system from the muscles by means of curara. If the increased metabolism is produced by the direct action of a ferment on the blood or tissues, or if it is merely due to the growth of bacteria, or if it is produced, as some think, through vaso-motor influences, it would occur after a feeble dose of good curara, which leaves heart and vessels intact, just as in normal animals, and would then be all the more significant because the metabolism is lowered in a curarised animal. ZUNTZ has endeavoured to solve this problem by keeping the animal in a bath of uniform temperature in connexion with an apparatus which permitted a careful collection and estimation of the amount of exhaled carbonic acid. The animals were then exposed to a pyrogenic agent, which in a normal animal caused a brisk pyrexia, with a corresponding increase in the gaseous absorption and excretion. Under the influence of curara, however, the amount of oxygen absorbed, and, as far as could be ascertained, that of carbonic acid eliminated, remained constant.

ZUNTZ admits that a negative result can only be allowed weight when the number of experiments has been large, but to it he has found hitherto no exception. Nor was there any exception to the uniformity with which febrile disturbance was produced in the control experiments by the pyrogenic substance injected. At first a decomposing infusion of hay was used, but in a subsequent series, for greater certainty, he inoculated the animals with blood from one recently dead from the septicæmia described by GAFFKY. He satisfied himself by experiment with the accuracy of GAFFKY'S statement that this virus causes, almost with certainty, the temperature to rise about eight hours after the injection, and that a few hours later a temperature of 105.5° F. is attained. In only a few instances among a large number of rabbits experimented on was the elevation of temperature slight and transient, although the microscopical examination of the blood showed the presence of the specific organisms, and death occurred in the course of forty-eight hours. With full consciousness of these possibilities of error, ZUNTZ believes that the number of experiments is now such that he can affirm the important fact that the one and only cause of the increase of oxidation processes in the body which occur in fever is dependent on the muscular innervation. Is, therefore, curara to take the place of the cold bath in hyperpyrexia?

## Annotations.

"Ne quid nimis."

### THE BRITISH MEDICAL ASSOCIATION.

THE jubilee meeting of the British Medical Association that has just been celebrated may prove to be memorable in many ways in the history of the Association. From all accounts it was one of the most pleasant gatherings that have taken place (although by no means the largest in point of numbers); and the interesting and beautiful district in which the members assembled was as much appreciated as the hospitality which the professional and municipal authorities of Worcester so lavishly bestowed. Of the actual gains to science accruing from this meeting it is not possible to speak with certainty; the sections were numerous, and in many of them subjects of wide interest were discussed in a more or less exhaustive manner. It has been said with truth that in such meetings there is too pretentious a programme attempted, and that the majority of the members subordinate the scientific labours to the opportunities afforded them of gaining an insight into the characteristic features of the district in which the meeting is held, its manufactures, its arts, and its natural beauties. There is so much to see and learn that is of wide human interest that comparatively few care to pay attention to the purely scientific work, which is the real *raison d'être* of the gathering. It might be well if the sectional work were more limited, and the opportunity seized for the consideration of a few special subjects, rather than for attempts to be made to secure a long list of communications, which are either doomed not to be read, or, if read, to be inadequately discussed. In his speech at the annual dinner, when proposing the toast of "Success to the British Medical Association," Sir James Paget dwelt largely upon the scientific work of the Association, as being the most important of its functions, and the one in which the greatest advances had been made, and he evidently desired to convey the impression that by a continued adherence to scientific investigations the Association would be doing work which ultimately would prove of greater advantage than by pursuing its political functions at the expense of science. The same spirit pervaded some of the addresses delivered by the presidents of sections, notably that of Dr. Allbutt in Medicine, of Professor Humphry in Anatomy, and Dr. Hughlings Jackson in Pathology, and certainly one of the greatest advantages of these gatherings is that the members can hear from men who have attained high positions by their own devotion to science, the underlying principles of scientific medicine. The general addresses were all pitched in the right key, and, as was fitting, each of the orators in turn indulged in retrospection, and in a certain amount of forecast. Dr. Strange, the President, in his able opening address, fearlessly pointed out the besetting evils of the present day, and did well to speak out plainly upon matters in which the honour and dignity of the profession are so vitally concerned. The reports of the committees that may be specially alluded to were that of the Scientific Grants Committee and that on Collective Investigation. In both these directions the Association is doing well to expend a portion of its funds. The work of collective investigation has practically only just commenced; but before the next annual meeting it is believed that the committee will be in possession of facts which will enable them to see how this useful work is really taken up by country practitioners. So far it promises well; and if energy and zeal on the part of its secretary be met by a like spirit among the profession generally the undertaking may prove to be the most valuable of any that the Association has yet ventured upon. It is, perhaps, hardly to be expected that in so large a body perfect

harmony should reign; and there is undoubtedly a growing discontent amongst the general body of members with the central management. This feeling managed to find expression on two occasions at Worcester, and Dr. Ward Cousins' motion respecting the *Journal* and Finance Committee received a certain amount of support. The growth of the Association of late years will only prove advantageous to it if the leading members, those in whom the conduct of the Association rests, are mindful of the interests of the profession, and the action of the Parliamentary Bills Committee with respect to legislation for the compulsory notification of disease shows how easy it is for them to put themselves into collision with the body of the profession. For although, theoretically, the Committee of Council is representative of all the branches, it is well known that the actual working members of that committee consist of a few whose time, duties, and places of residence enable them to attend its meetings. The wider, then, the Association extends its limits the greater will be the demand for securing a thorough representation on its governing body of all its branches; and, unless those at present in authority exert themselves to satisfy this desire, the opposition to the present régime will grow to such an extent as to be disastrous to that harmony which alone can maintain the Association in the position it ought to occupy. Therefore this Worcester meeting may prove to be, in more senses than one, a landmark in the Association's history, and the next few years may witness the inauguration of changes of the greatest moment in its constitution.

### THE PRESIDENT'S ADDRESS AND THE LATE MR. WAKLEY.

AN old and esteemed correspondent writes:—The learned President of the British Medical Association can hardly be complimented on his choice of simile at that point of his address at which he speaks of the first days of THE LANCET. When he describes a weasel or polecat biting, scratching, and driving out bats, he gives us a picture of the habits of those animals which dear old Goldsmith himself would hardly have dared to introduce into "Natural History"; and when he describes these animals as engaged in hanging up the bats like vermin on a barn door, natural history altogether lapses into such fable as "Alice in Wonderland" might very much like to work into a new edition. Dr. Strange, however, may be forgiven this, and a great deal more, for the kind manner in which he has spoken of the founder, the projector, and for so many years the Editor of THE LANCET, the late Mr. Thomas Wakley. Dr. Strange says, the services which that journal, after it had conquered its own independence, rendered to medicine, was simply incalculable. Monopolies destroyed; hole-and-corner meetings and doings of the corporations, for the benefit of the few to the detriment and exclusion of the many, exposed; pompous ignorance and overbearing imbecility held up to scorn; the oppressed and obscure, but honest and industrious, seeker after truth brought to the front; the attack on the Legislature, its apathy towards all that concerned the interest of our profession, its tolerance of abominable monopolies and abuses in high places; the farce of the Coroner's Court; the winking at the adulteration of the food of the people; the inhuman neglect of the sick poor; the disregard of all decency in the burial of the dead;—these abuses, said the President, were one by one attacked and their authors and abettors lashed with a pitiless and unsparing hand, until redress and reform were grudgingly conceded. To these kind, and it may, with perfect truth, be said honest recognitions, others might have been added. For example, there was nothing so grateful to the founder of THE LANCET as the recognition of the service which he rendered to the British soldier. The writer of this note sat some

quarter of a century ago by the side of Mr. Wakley in a crowded assembly. A distinguished literary man of the time had interrupted the conversation for a moment by a congratulatory word to the Coroner for Middlesex in respect to his services in suppressing the brutal practice of flogging, literally to death sometimes, men belonging to the army service; and when we resumed our talk the first word uttered by Mr. Wakley was to the effect that he had rendered no public service for which he hoped to be so much remembered. Dr. Strange, in a further recollection of the past, draws a contrast between the founder of THE LANCET and the founder and editor of the once famous *Medico-Chirurgical Review*, Dr. (afterwards Sir John) Forbes. The contrast is, no doubt, a striking one. Mr. Wakley was all verve, action, fire; Dr. Forbes was all quietude, repose, reflection. Mr. Wakley was from the beginning to the end of his career constructive; Dr. Forbes from the beginning to the end of his career was analytical. Mr. Wakley was a leader writer; Dr. Forbes was a reviewer. Mr. Wakley did not wait for men to finish writing what was foolish or mischievous, he attacked them while they were at it; Dr. Forbes waited until they committed themselves to paper, and then tore them to pieces if he did not agree with them, with a skill and deliberateness which had few parallels. Mr. Wakley's genius lay in comprehending the present, that which was before him, and in discriminating between the good and the bad as it existed at the time; Dr. Forbes' genius consisted of insight, detection of concealed difficulties, and foresight of changes and difficulties that were to come. Mr. Wakley, though severest of severe critics in public work, was gentle in nature, essentially good tempered, and never put out, whatever might occur. He slept annoyances down. Dr. Forbes was of a quiet nature too, but with a certain irritability which he could not repress, and a weariness he could not conceal. At the same time both men had much that was in common. Both had this admirable trait, that they were considerate for all men younger than themselves whom they had learned to appreciate. Both had the happy faculty of distinguishing the working men from the drones; the real men from the pretenders. Both had energy, endurance, courage, perseverance, and each in his respective way loved nothing so well as the profession which it was their part to raise to a nobler standpoint, a more useful service, and a more befitting position than it had ever attained in English history.

The journal founded and edited by Sir John Forbes has for some years ceased to exist, failing to meet the current want or current tastes: a fact which everyone must regret; for the tone of the *Review* was classical, practical, cultivated, and perhaps, after all, required nothing more than the hand of its projector to keep it alive. The momentum given to THE LANCET by Mr. Wakley is still felt through every column of the journal, which now commands a larger circle of readers, both professional and lay, than he ever addressed. The spirit in which he conducted it is religiously, it may be said filially, preserved under the present Editor, who has the gratification of seeing its influence extending, its size having been amplified threefold, and its services as the leading medical and sanitary power acknowledged throughout every English-speaking community in the civilised world.

#### GUY'S HOSPITAL AND CRITICAL CASES.

OUR readers are aware of the circumstances of the refusal of the house-surgeon of Guy's Hospital to retain or admit John Tyson, found by him among the out-patients to be labouring under small-pox. It is to be regretted that after detecting so grave a disease the resident medical officer, though we admit the limitation of his powers, did not retain the man in some isolated place, or send him in a cab—with instructions for its disinfection

to follow—to Stockwell. After he was dismissed, Tyson got into an omnibus and went to Stockwell, thereby breaking the law by exposing himself while knowing himself to be labouring under infectious disease. These facts have been under the consideration of a Committee of the Metropolitan Asylums Board. One or two members of the Board thought the hospital authorities deserving of censure. But the Board has contented itself with arriving at one or two practical resolutions—viz., that every hospital should have an isolation room in which to place a doubtful case; secondly, that it be recommended to the Local Government Board that patients be received at the Metropolitan Asylums Hospitals on the certificate of the resident medical officer of any of the London hospitals. We ourselves have carefully pointed out the necessity for these and other changes in connexion with this painful case. The fact is, that the whole arrangements for the conveyance of the infectious sick, and of the sick and wounded generally, are very clumsy and circuitous. We want an ambulance system in London similar to that which they have in New York, where, by ringing a bell, an ambulance apparatus from any hospital can be secured in a few minutes.

#### THE EGYPTIAN EXPEDITION.

THE greater number of medical officers and the Field Hospitals have now embarked for Alexandria, the 2nd Bearer Company, under the charge of Surgeon-Major O'Dwyer, with Surgeon-Major J. Walker, Surgeons R. V. Ash, B. Connolly, A. Harding, P. Connolly, E. D. Farmer, R. C. Laffan, Lieutenants of Orderlies D. O'Connor and Tighe, and 143 non-commissioned officers and men of the Army Hospital Corps left Portsmouth in the *City of Paris* and *Texas* on Saturday last.

Surgeon-Majors R. P. Fergusson and W. Cairns left the Albert Docks on Monday, in charge of the troops on board the *Lydian Monarch* for Alexandria.

Deputy Surgeon J. J. Clark, Bengal Medical Service, proceeds with the force from Bengal to Egypt in charge of the 1st Division.

Surgeon J. C. Dowman has proceeded to Egypt in the *Adjutant*, which left the Albert Docks on the 17th inst.

The steamship *Courland* has been placed at the disposal of the medical authorities by the Admiralty for service as tender to the hospital ship *Carthage*; she will be fitted with cots to accommodate thirty sick and wounded and is now on her way to Cyprus, where the dépôt of the Army Hospital Corps will be formed, and which will be constituted an important base and reserve. Deputy Surgeon J. Lamprey will superintend the medical arrangements on the island.

#### "THE COSTLINESS OF MEDICAL WORKS."

DR. BARRON, of Southport, whose letter appeared in our last issue, enters a strong, and perhaps not wholly groundless, protest against the costliness of medical works. He regrets, and doubtless every one of his readers will join him in deploring, the fact that because medical works are, as a rule, expensive they are not extensively purchased, and probably not generally read. The medical libraries do something to circulate works on medical and surgical subjects among the profession; but it is notorious that practitioners do not, as a rule, possess large collections of the volumes published for their enlightenment. We confess that our own view of this matter is not precisely that taken by our correspondent. We admit that the high prices charged for professional works may, and doubtless do, to some extent, limit their sale, but we doubt whether the total number of books sold would be greatly increased if their cost were even considerably less. It is impossible to disguise the fact that the medical calling is one which makes a proportionally larger

demand on the mental attention of its members than almost any other. The busy practitioner finds his time very fully occupied, and the few occasional moments of leisure from actual clinical business which he can command scarcely suffice for the study of such reports of cases, reprints of papers read and discussions taking place at the Societies as appear in the medical periodicals, and those special works which, so to say, force themselves—whether cheap or costly—into every medical man's book-room. If, which rarely happens, the practitioner has spare time on his hands, he is likely to follow the bent of a cultivated taste, and find pleasure in the perusal of ordinary literature. Although we would not be misunderstood in this respect, we doubt whether it is not one of the needs of the social epoch as regards the status and popularity of the profession that even greater attention than is now commonly devoted to general literature should be so bestowed. It is notorious that medical men are apt to be single-barreled in their conversational powers, because they have little or no time to read or think on other than their own technical topics. Practically this gives them too distinctive a character in society. It is not as a rule possible instantly to recognise the barrister or the clergyman, unless the latter persists in the ridiculous custom of going about marked by the cut of his clothes. It is, however, almost invariably possible to spot the medical practitioner in any social gathering, because he looks and talks "shop" in default of being *au courant* with other subjects, except as they may be incidentally touched from his own standpoint. We are, therefore, less desirous that medical men should be further burdened with their own particular literature than that they should be able to find time and inclination to make frequent excursions beyond its special province. For the rest, it need only be urged that medical books are, as a rule, more costly to publish than other works, and because the sale is very limited the price is high. Standard or classical—in a word, necessary—works may be issued at low prices, but the bulk of medical books cannot be published cheaply unless authors are prepared to lose heavily by their issue. The only recompense for such a sacrifice would be extension of personal popularity and increase of practice; and it is the special desire of the profession just now to discourage as far as possible the publication and sale of works which are practically advertisements. The question raised is one that needs to be looked at all round.

#### VASO-CONSTRICTOR NERVES.

AN elaborate study of the sympathetic nerves which cause the dilatation of the vessels of the mouth and lips has been made by MM. Dastre and Morat. Two years ago they announced the discovery, in the cervical trunk of the sympathetic, of filaments, the function of which is to cause dilatation of the vessels of one region of the head, and thus to antagonise the action of the other fibres of the sympathetic. If the spinal cord is divided in the lower part of the neck, stimulation of the posterior segment causes a primary dilatation of the vessels of a large part of the head, especially in the region of the ear and of the mucous membrane and skin of the nose and mouth. The result is the same in the cat, rabbit, hare, and dog, and seems to show that vaso-dilator nerves arise from this part of the spinal cord. If the dorsal nerves from the second to the fifth are exposed, divided, and the peripheral ends are stimulated, dilatation of vessels occurs, but in a limited region of the mouth and face, and only in the dog. The result only follows stimulation of the anterior roots. Hence, in this animal at any rate, the vaso-dilator nerves seem to leave the cord by this path. A similar experiment with the branches from these roots to the sympathetic gives the same result and conclusion, and may,

in like manner, be followed up the cervical sympathetic trunk. Many fibres were traced by the experimental method into the fifth nerve. The course of the nerves being thus ascertained, an attempt was made to excite them by an agent less artificial than electricity. Asphyxial blood is a powerful stimulant to the central nervous system, but it stimulates both classes of vascular nerves, and one or the other effect may predominate. In the bucco-facial region the effect of asphyxia is congestion. If the sympathetic is divided on one side, the congestion is much lighter, sometimes is absent. Hence the asphyxial vascular dilatation must be due, in part at least, to the influence of these sympathetic fibres. A dilator action may also be excited by reflex influences. Stimulation of the central extremity of the divided vagus, isolated from the sympathetic in the lower part of the neck, causes a primary and bilateral dilatation, which is lessened or prevented by preceding division of the sympathetic. It is also prevented if complete muscular relaxation is produced by the inhalation of chloroform, or if the spinal cord has been divided. It is especially considerable if the stimulation is applied to the superior laryngeal nerve, or to the trunk of the vagus, as far as the origin of the pulmonary branches, but is almost absent when the stimulation is below this point. Bucco-facial congestion may also be produced by excitation of the central end of the sciatic or of the tibial nerve, and probably also of other cutaneous branches. A certain degree of congestion is produced by asphyxia, and by reflex excitation, after the division of the sympathetic; and when sufficient time has elapsed to permit the degeneration of the nerve fibres, stimulation of the superior maxillary nerve still causes a certain degree of congestion of the corresponding lip. Hence the cervical sympathetic appears not to contain all the vaso-dilator nerves of this region. In this respect the dilator nerves of the vessels resemble the dilator nerves of the iris, which run in part only in the sympathetic trunk.

#### THE DROWNING SEASON.

THE season of deaths by drowning has arrived, and it has been most painfully signalled this year by the untimely death of a distinguished man, who was as greatly respected as he was widely known. Professor Jevons stood on the verge of a great philosophic success when he met his death under circumstances peculiarly painful to his family and his friends. He went out to bathe in perfect health and spirits, and his body was found a few hours afterwards, life being totally extinct. It is not much use in a case like this to ask whether the deceased over-estimated his powers as a swimmer, or did not realise the special risks of the coast. There is always danger in bathing. On the sands at Boulogne the tide may come in suddenly, and sweep away the machines. At any one of our English watering-places an under-current may throw the most cautious bather and carry him out of his depth. If it be cold a man may get cramp. If it be hot he may be suddenly attacked with apoplexy, or be struck down with sunstroke. The perils of the sea are many and ever present. There is only one policy of self-protection, and that, unfortunately, the majority of persons will not adopt. The use of a swimming collar, or waist belt, or any other contrivance which might help to keep the head above water in a moment of danger, and so preserve the wearer from drowning until assistance arrived, is considered beneath the dignity of anyone who ventures into the water. Want of moral courage to take proper precaution lies at the root of most personal "accidents." It is very little, if any, use to offer this remark, because even those who acknowledge its accuracy will not be practically impressed by it. We can only lament these sacrifices of life to the passion of independence. The death of Professor Jevons will cause widespread

regret, and in a certain melancholy way it may help for the moment to emphasise the warning which year by year it is our wont to give.

#### HEALTH OF THE PRINCE OF WALES.

THE facts concerning the health of the Prince of Wales, recently commented upon, are simple, and it is well that they should be stated simply. His Royal Highness has had a great deal of work lately, and, like other men who are somewhat jaded, he has been recommended to embrace the opportunity offered by the season and family arrangements to visit a pleasant locality, and while there to do as the rest of the visitors will do—that is, “take the waters.” The change of scene and climate, the rest, and such modifications in his mode of life as are necessitated by the sojourn at a German bath, will, it is hoped and believed, be of service to His Royal Highness. There is really no more to be said about the matter, except to express the loyal wish that the “treatment”—if treatment this can be called—may be successful. The Prince leads a life which is exhausting, and he needs rest. That rest may be enjoyed where he is going, and, in all human probability, his Royal Highness will enter upon his autumnal sports all the better for the preliminary trip he is about to take.

#### HOMŒOPATHY AND THE BRITISH MEDICAL ASSOCIATION.

THE authorities of the British Medical Association may congratulate themselves on escaping so easily from an embarrassing position in reference to the question of homœopathy. The injudicious allusions to it last year by Dr. Bristowe and Mr. Hutchinson respectively, by mutual understanding and with the concurrence of the Council, placed the Association in a very painful position. It was not to be supposed for a moment that a great medical Association, having the same opinion and the same laws, in regard to homœopathy, held and practised by scientific medical men all over the world, could quietly let pass such advice as was administered to it by gentlemen who only looked on the subject from an academic and benevolent point of view. It is not now—when homœopathy is extinct; when the real disciples of Hahnemann in England can be counted on one's fingers; when these say that homœopathy is no longer taught, even in the School of Homœopathy; when the contempt and denunciation of homœopathy have received their triumphant vindication—that a great medical Association should have been asked to show any quarter to medical men who still either believe in the exploded nonsense or trade on the belief of non-medical persons who do so. But this was the suggestion of the authors of the address in Surgery and the address in Medicine last year. And when the members of the Association would naturally have risen to protest, they were given to understand it would not be courteous to express their dissent then and there. Many significant indications have been given to the Council that the members of the Association would not allow themselves twice to be found in such a childish and false position. It is not one of the notes of liberal profession to tolerate either false principles or those who trade on them. Accordingly, the Council, in its report at the recent meeting, dealt boldly and candidly with the members on the subject, and announced rules which will make it impossible for a homœopath henceforth to become a member of the Association. Mr. Nelson Hardy wished to go further. He wished to so alter the resolution adopting the report as to secure that the removal of a belief in homœopathy, or of any other designation implying a special mode of treatment, should *ipso facto* disqualify for membership of the Association. The Association was content to be assured that the new rules would hence-

forth exclude all homœopaths. If any homœopath now chooses to remain a member, he may; but his sense of dignity will be a subject for the study of his fellow members. Here this question will end for the present. There is only one way in which gentlemen now using the title and the shibboleths of Hahnemann can be admitted to Medical Societies, and that is by ceasing to use them. It is they who raise the sect and import narrowness into medicine. It is they who exclude themselves. They would not be owned even by Hahnemann. They have abandoned the fundamental points of his faith and practice. Let them act candidly with the public and abandon a name which misleads it, and they will find no want of magnanimity in the profession to which they return.

#### DWELLINGS OF THE POOR.

POLITICAL exigencies have hitherto intervened to prevent the present Government following the example set by their predecessors in matters of sanitary reform. The Bill, however, dealing with the question of artisans' dwellings, which has just received the assent of the Queen, is a piece of domestic legislation which is likely to be attended with beneficial and important results. The Act of 1875, introduced by Sir Richard Cross, has not worked so efficiently as was expected, owing to its being hampered with the regulation requiring that the whole population displaced should be provided with accommodation within the same area. The present Bill affords relief in this respect, since accommodation for only one-half the population displaced need now be provided. This will considerably lessen the cost to the ratepayers—a consideration which has hitherto prevented improvements being carried out as extensively as was contemplated. There is one provision in the new Bill, however, which, we fear, will require to be reconsidered. Formerly all expenses connected with putting the Act in operation has been borne by the Metropolitan Board of Works; now, when areas containing less than ten houses have to be dealt with, the expenses are to fall upon the local rates. There can be little doubt that many districts are too poor to expend the necessary sums, and these districts will be found to be generally those in which nests of objectionable tenements abound; the expenses therefore entailed on these parishes would be out of all proportion to the rates required from the general population of the metropolis. It seems only fair that the expenses of improvements intended to benefit the whole community should be equally distributed. If the wealthy inhabitants of the West-end wish to diminish the risk of zymotic disease being imported to their mansions, they must see that the dwellings of their poorer neighbours are maintained in a wholesome condition in less wealthy and fashionable districts, and expect to pay a fair share for the protection afforded. The Bill, however, will give a considerable impetus to the improvements already in progress, and with the erection of dwellings of a superior order in the metropolis, together with the facilities afforded by the railways for those whose avocations permit them to go a little way out of town for cheap and decent quarters, it is to be hoped that the artisan class will soon be provided with ampler accommodation, and that the terrible injury both to health and morals which overcrowding, together with insanitary and squalid surroundings, engender, will gradually diminish and finally become extinct. But although hopeful for the future with regard to the house accommodation of the artisan class, we fear the Bill will fail to benefit the very poor. When the present rookeries and alleys in which they now herd are swept away, where are they to find a refuge? The rent of rooms in the buildings which replace them will, we fear, be too costly for them, and they will crowd together more closely in the dens that remain. It will be a source of

but little satisfaction if, after considerable expense, we find that we have given one class more elbow-room at the expense of another. It is to be hoped that those who have charge of the carrying out of the Artisan and Suburban Dwellings Acts will not be too ambitious in their schemes, but will bear in mind the needs and requirements of the very poor. In fact, they should be the first consideration. The mechanic with his regular wages and tolerably sure employment, would not, as a rule, find it difficult to arrange to live in the suburbs, but to the very poor, whose wages are scanty and often very precarious, such a proceeding would be impossible.

#### RIDER'S SPRAIN.

WE have recently had attention drawn in our columns to an accident not infrequent in the hunting field and among riders, the true nature of which has not hitherto been pointed out, while its treatment has for the most part remained entirely in the hands of the surgical instrument maker. Everyone not constantly taking horse exercise is well aware of the strain upon the adductor muscles that "gripping" a horse occasions. This strain leads to pain and tenderness along the inner side of the thigh and over the tendon of the adductor longus in particular. This is occasioned by the prolonged and unaccustomed use of this group of muscles. If during hunting or riding, from some movement of the horse, a sudden and severe strain is thrown upon these muscles, the adductor longus is apt to yield, and a rent occurs in it just where the narrow tendon joins the expanding muscular tissue. The immediate symptom is severe pain in the part with or without a sensation of a snap, and inability to maintain one's "seat." The torn bloodvessels pour out blood, and an extensive bruise or even a blood tumour may result. The treatment consists in rest and such applications as will most quickly lead to absorption of the effused blood and healing of the breach in the muscle. Equable pressure fulfils these aims, but some would prefer the previous application of cold to the part. Subsequently some means of applying firm pressure along the upper and inner part of the thigh is necessary during horse exercise. This allows the contraction of the adductor muscles without pain or a sense of weakness. For the purpose special appliances are manufactured, but riders have found a not inefficient substitute in a girth or stirrup leather. The accident is stated to be more common in civil than in military life, and in different cases it varies very much in degree, in some a great part or the whole of the muscle being torn, in others only a few of its fibres.

#### MONSTROSITIES IN THE PUBLIC STREETS.

A CORRESPONDENT asks if there is any Act of Parliament which prohibits the parade of monstrosities and deformities in the public streets. Unfortunately there is not. Such an Act is much needed. Great harm may be done by the exhibition of revolting spectacles to the general community. We can only express our regret that there should be no law capable of being applied to the mitigation of the nuisance of which he complains. Not only are many of the pitiable objects to be seen in the streets of London and other large cities hideous and sickening; they cannot be witnessed without the production of an impression on the nervous system which is likely enough to be mischievous. In certain cases, not only may the individual suddenly be brought under the influence of such an impression, and be injuriously affected, but, by the operation of well-known laws of development, the very monstrosity or deformity reflected on the sensorium may be reproduced in another generation, passing from mother to unborn child. This is a matter of considerable moment, and should help to draw the attention of public authorities to the need of a prohibitory law.

#### PROFESSOR ESMARCH ON THE CASE OF PRESIDENT GARFIELD.

PROFESSOR ESMARCH delivered a lecture on the treatment of President Garfield's wound before the Physiological Society of Kiel in February last. This lecture he has now printed and circulated, and it is impossible that the views of a surgeon so accomplished and so worthy of expressing an opinion on such a case should not be canvassed. The facts of the case are first of all clearly and fairly stated from Dr. Bliss's own published accounts of the progress of the case and of the post-mortem examination. Professor Esmarch's conclusions are (1) that the wound was not in itself absolutely fatal; (2) that the bullet was not the cause of the septic suppurative in the wound which led to the fatal result; (3) that the cause of the septic suppurative was introduced from without, and that as contributing directly or indirectly to this were the following errors in the treatment—the repeated probing and examination of the wound with instruments and fingers not rendered aseptic, the failure to dress the wound aseptically, the syringing out of the wound with fluids not sufficiently antiseptic, and the failure to give a complete vent to the "bagging" pus; (4) there was no true pyæmia, but only metastatic inflammation of the parotid gland; (5) the cause of death was hæmorrhage, moderate in amount, but occurring in one whose strength was undermined by septic fever, decubitus, bronchial catarrh, and hypostatic pneumonia; (6) although the splenic artery may have been injured primarily by the bullet, or by a splinter of bone, this would not have led to the formation of a false aneurism except for the establishment of putrid suppurative. In conclusion, Professor Esmarch refers to the popular superstition that the bullet is the cause of all danger in a gunshot wound, and that to extract the bullet should be the chief aim of the surgeon. He asserts that most of the secondary dangers arise rather from the fingers of those who explore the wound, and that the American surgeons committed the error of doing too much rather than of doing too little, as they have been freely accused of at home. Finally, he surmises that if no search had been made for the ball, and the wound had been dressed aseptically, the unfortunate patient would have been alive now. Valuable as is Prof. Esmarch's opinion on such a point, we regret that this lecture has been published, at any rate so soon. It would not have lost in value by being kept back until the acrimonious discussions on the conduct of the attending surgeons had died out on the other side of the Atlantic. It is proverbially easy to be wise after the event, and it is an ungracious task to criticise adversely the conduct of men who, under very trying circumstances, were suddenly called upon to act in a grave emergency. We are willing to admit that mistakes may have been committed, but it is a case in which the golden rule is eminently applicable: "Let him that is without sin first cast a stone."

#### GASTRIC ULCER.

IN the course of some experiments on the production of nephritis by the injection of cantharidin under the skin, Aufrecht has made the remarkable discovery that ulceration of the stomach may result from these injections. After the subcutaneous injection of cantharidin, suspended in oil to lessen the local irritation, he found in guinea-pigs a large number of circumscribed changes in the mucous membrane of the stomach. These were at first regarded as merely hæmorrhages, but on closer examination were found to be spots of loss of substance, the boundary of which projected above the level of the adjacent mucous membrane. These changes were especially conspicuous in the stomach of a rabbit, which died ten days after the injection of two and a half milligrammes of cantharidin. About fifteen small

ulcers were found in the stomach, many of them with raised edges, and all filled with blood-clot. There were also six circular spots of a dull grey colour, sharply limited, without any extravasation. A microscopical examination showed in the latter the following changes. The epithelium of the glands was paler and less granular than normal. Between the glands was a clear amorphous material; the capillaries were distended with blood, whereas, elsewhere, they were empty. A similar change was found in the vicinity of the extravasations, and the glandular epithelium here presented irregularity. The extravasations were of uniform brownish-red blood, in which no intact blood-corpuscles could be seen. There was no sharp limitation to the blood effused, such as might have been expected had the hæmorrhage resulted from the rupture of one vessel. From these facts he concludes that the extravasation is the second stage in the process, consecutive to inflammation, which appears to be the first alteration. Anfrecht believes that these facts indicate that in man a similar sequence may obtain, and that ulcer of the stomach probably commences as inflammation, and not, as is commonly assumed, by hæmorrhage.

#### ISOLATION HOSPITAL FOR RAMSGATE.

FROM the last report of the proceedings of the Ramsgate Improvement Commissioners, we fear that this body is about to take a retrograde step. Some years ago the Commissioners joined Margate and Broadstairs in erecting a hospital for infectious diseases, but they unfortunately delayed action too long, and a temporary wooden structure was hurriedly put up in face of an epidemic of small-pox. The building, though a good one, has long been found ill adapted to many purposes to which such a hospital may be put at a seaside resort, and complaints have been made as to the lack of accommodation available. Hence for some two years or more a permanent extension has been talked of, and a joint hospital committee appear to have done their best to carry it through. After many delays the scheme has come before a Ramsgate committee, and their report, which shelves the question, has been adopted by the Commissioners. The grounds for this unfortunate proceeding are in some respects curious. The extension is regarded as "hazardous and inopportune." With regard to its being hazardous, we find the chairman of the Ramsgate committee explaining that temporary buildings could be erected if an epidemic broke out in the town. We certainly fail to understand what is here meant. If infectious hospitals ever do harm to their immediate neighbourhood, and are hence hazardous, it is when large numbers of patients are aggregated together; and the chairman, if correctly reported, instead of proposing the erection of a building containing a small number of beds in which to isolate a few attacks, and so to prevent an epidemic, would literally wait till the epidemic is prevalent, and then attempt to deal with the large number of patients which previous neglect of isolation will have rendered possible; thus risk of danger, if any exists, is courted. How this scheme can be inopportune we also fail, from a medical point of view, to see. Medical men have at times hardly known what to do in order to secure the isolation needed for these prosperous Kent coast watering-places, and yet the remedy is again postponed. The district in question ought also to have had sufficient experience of temporary buildings, for those at first erected were not ready to deal with the epidemic which led to their construction; and we would warn Ramsgate against further procrastination in this matter, which may at any moment be of vital importance in so far as its first interests are concerned. The town is stated to be at present remarkably free from infectious disease, and there is plenty of room at the hospital; but the reverse has been the case, and may be so again.

#### THE FOURTH INTERNATIONAL SANITARY CONGRESS.

THE first international congress of sanitary reformers was held, it will be remembered, some eight years ago at Brussels, the King of the Belgians presiding. The second congress met at Paris, under the patronage of the French Government, during the Universal Exhibition of 1878. It was a most brilliant gathering of some five hundred adherents representing eighteen nationalities. They met at the Palace of the Trocadero, and subsequent results have proved that the debates were not futile in producing practical improvements. The third congress, held at Turin in 1880, was also a great success. The Italian Government lent its aid, the King of Italy in person attended at some of the meetings. And now the fourth congress will be held at Geneva, from the 4th to the 9th of September, together with an exhibition of sanitary appliances from the 1st to the 15th, in the large military buildings of the Plain Palais. The programme of the congress, with a synopsis of the opening speeches of each section, has already been published in pamphlet form, and notification of adherence, together with a subscription of twenty francs, should be sent before August 31st to Doctor P. L. Durrant, 4, Rue Pinto, St. Pierre, Geneva. In exchange for this modest subscription, a printed and elaborate report of the proceedings of the congress will be received, and its members benefit by the arrangements made with the Swiss, Italian, and French railways. Delegates from England, we understand, will, while paying full fare to Geneva, receive a free return ticket from Geneva to Calais. The organising committee will, if required, secure rooms for visitors. The Congress is to be held at the Geneva University, and there will be a club room at the disposal of the members for writing and receiving letters, &c. Excursions on the lake of Geneva have been organised, and there will be no lack of those usual festivities that enliven gatherings of this description. We will give a summary, on a future occasion, of the subjects selected for discussion, and, perhaps, as this is a tempting season for a visit to Geneva, England may be more fully represented than at previous International Congresses. The majority of adherents are, of course, medical men, but all whose scientific studies are connected with the preservation of public health are welcome, and this includes architects and sanitary engineers.

#### "DOUBLE SUICIDES."

A VERY important question is raised, or rather revived, by the occurrence of "double suicides;" of which we have recently had a conspicuous example. When two persons conspire together to kill each other, or to destroy their several lives simultaneously—it matters not which of the two forms of resolution may be adopted—it is simply absurd to suppose they are insane. The penalties entailed by a verdict of *felo de se* are, however, so revolting, that juries make ridiculous returns rather than bring in a proper verdict. It is not impossible, but it is in the last degree unlikely that a case of double suicide should have been one of double insanity. The only way this could happen would be by the morbid influence of one mind on another anterior to the commission of the act. There may be such cases, but they are so rare as to render it unreasonable to take the bare probability into account. Some years ago a case was reported in which two members of the same family became insane on the same subject, and for a considerable time played into each other's hands in the matter of a common delusion as to rank. There is, of course, no psychological reason why these two lunatics might not have conspired to kill themselves, but the conjunction of mind and purpose is extremely unlikely to have taken place. In making this remark we are not unmindful of the cases of double insanity and double suicide which have

been recorded. A closer scrutiny of the last-mentioned class of cases would probably lead to their more precise classification as instances of murder and suicide. However this may be, it is time that the law which induces juries to regard almost every case of suicide as one of insanity should be repealed. It is a disgrace to our statute-book, a perpetual offence to the common sense of the community, and of no deterrent influence as regards the crime of self-murder, because it is practically sure to be evaded.

### CONTAGIOUS DISEASES ACTS.

THE annual report by the Assistant Commissioner of Police on the operation of the Contagious Diseases Acts during the year 1881 appears opportunely, just as the report of the Select Committee on the subject is attracting attention. The results for the year are very satisfactory, showing as they do a decrease in the number of registered prostitutes and in the number of brothels in the protected districts. During the year, of 489 prostitutes who came into these districts from places not under the Acts, 322, or 65.8 per cent., were found to be diseased on their first medical examination—a strong proof of the necessity for some check upon the means of spreading so frightful a disease. The beneficial influence of the Acts is shown by the fact that 74 young girls under eighteen years of age, 86 women from eighteen to thirty, and 4 above thirty, who were found in bad company and improper places, but had not commenced a life of prostitution, were rescued; while 32 under eighteen and 97 above that age, “who had commenced an immoral life, abandoned it on being cautioned by the police.” There are numerous tables appended to the report which show clearly a large reduction in the numbers both of women and brothels in all the districts since the Acts came into operation. In 1866, when the Act was passed, there were in the subjected districts 135 prostitutes under sixteen years of age, and of these nearly one-fourth were under fifteen; while in 1881 there were none under the latter age and only 6 under sixteen. There has also been a very great reduction in the number of public-houses and beerhouses where common women resided, or which were provided with accommodation for the purposes of prostitution. In the last ten years such public-houses have been reduced from 98 to 12, and beerhouses from 40 to 3. If a longer period than ten years be taken, the reduction is still more striking. Of the 12 still existing there are 8, and of the 3 one, in the Chatham district. Such a fact is far from creditable to the magistrates with whom the power of granting licences rests, and furnishes a strong argument in favour of giving more power to the police towards effecting the suppression of such haunts of vice. We are glad to observe that the duty of the police specially employed under the Acts has been very satisfactorily discharged, there having been only one case of excess or violation of duty brought to notice during the year.

### DR. RICHARDSON AND THE EISTEDDFOD.

DR. B. W. RICHARDSON is to deliver the inaugural address of the great Welsh festival, the national Eisteddfod, which opens at Denbigh on Monday next, the 21st inst. The Eisteddfod has been held, it is said, since the fifth century, representing largely, and, indeed, almost exclusively, the arts of music and poetry. For a few years past a new section has been introduced devoted to the discussion of subjects of scientific and social importance, and now the festival is opened by some public man, statesman, or man of science or letters on the invitation of the organising committee. This year the choice of an orator fell on our medical confrère, who will have, it is expected, one of the largest audiences he has ever addressed.

### AMBULANCES FOR THE METROPOLIS.

WE have received a paper by Mr. John Furley on the use of ambulance litters and horse carriages for the removal of sick and injured persons, especially in reference to the metropolis, which he read before a recent general assembly of the Knights of St. John of Jerusalem. After recounting the efforts of the Association to instruct the public in rendering efficient first aid to the wounded, and to provide ambulances at the police stations, Mr. Furley states: “I am of opinion that telegraphic or telephonic communication between the City and metropolitan police stations and hospitals, though it might prove occasionally advantageous, is not absolutely necessary, and that the establishment of fully-equipped ambulances in connexion with the metropolitan hospitals would entail a very large annual expenditure, which none of these institutions would be justified in incurring. But it cannot be denied that some steps should be taken to facilitate the removal of sick and injured persons, and I can but think that this want will best be met by developing the system already commenced by the St. John Ambulance Association, and placing the best stretchers and litters at police and fire brigade stations, and at other convenient places; and that at certain points, especially in the suburbs, horse ambulance carriages should be stationed ready to be sent out at short notice.” Mr. Furley urges the formation of properly trained bands of volunteer ambulance helpers in towns and villages to conduct the removal of sick and injured persons, and appends the rules of some such bands already formed. The paper may be obtained on application at St. John's Gate, Clerkenwell.

### GASTROSTOMY.

ON the 21st ult. Sir William Mac Cormac performed this operation, at Hackney, on a gentleman aged fifty-five years (a patient of Dr. Daly), who had malignant stricture of the œsophagus. The operation, as well as the subsequent dressings, was performed with the strictest antiseptic precautions. The procedure was divided into two stages, the stomach not being opened for fourteen days from the first operation. The temperature never rose above 98.6° or the pulse above 80. The patient, during the fortnight, was fed by the rectum, defibrinated bullock's blood being chiefly used for this purpose. The patient recovered without any unfavourable symptoms. He was up sixteen days after the operation. He is now fed through the opening in his stomach four times a day; he has a pint of milk, with a couple of eggs, or a pint of beef-tea or soup, at a time. He is gaining flesh and is in good spirits. Further details of this case will be published hereafter.

### THE PHRENIC NERVES.

THE effects of lesions of the phrenic nerves have been studied experimentally by MM. Henocque and Eloy. The effects on respiration of injury to one or both were registered on recording apparatus. The immediate effect of a lesion of one nerve was found to be a change in the respiratory rhythm, the movements being at first rendered more energetic. After a few moments the diaphragm ceased to move on the side which had been injured, and the contractions of the inferior intercostal muscles and accessory elevators of the upper ribs were rendered feeble. The experiments were made on animals in which the respiration is both abdominal and costo-abdominal—the dog, cat, guinea-pig, and the monkey. Death often rapidly follows an injury to the phrenic nerve, but some animals survive, and the thorax is then motionless on the corresponding side, especially in the cat and the monkey. The respiratory movements become visible a few days afterwards, and are of course due

only to the intercostals. At a later period, during the reparation and regeneration of the nerves, the tone of the voice was observed to be altered. Respiratory tracings taken two, four, and ten months afterwards showed the gradual return of the respiratory curve to the normal. But even when the rhythm was restored, the movements continued deficient in extent. Moreover, in spite of the regeneration of the nerves, there remained an hypertrophy of the inferior intercostal muscles, set up by their supplementary activity.

#### HOSPITAL ACCOMMODATION IN SOUTHWARK.

WE have been at some pains to inquire into the recent case of burn in an out-patient, who died while under treatment at Guy's Hospital. The case was that of a little child one year and ten months old, suffering from burns on both arms. It was dressed in the casualty-room, attended again the next day, was redressed and sent home, where it died on the following morning. It appears that while it is the usual practice at this hospital to admit all such cases, it has been found necessary, owing to the large number of applicants for admission, to send many accidents to other institutions, while in a few an attempt has been made to relieve by outdoor assistance. At the present time we find that several surgical wards have two, three, and even four over the regulation number, so that while every effort seems to be made to meet the demand for relief, it must remain impossible to accommodate many of the cases which flock to the hospital. It may be mentioned that the population of the district in which Guy's and St. Thomas's Hospitals are situated has increased more than a million and a quarter since the beginning of the century, while the hospital accommodation has remained almost at a standstill.

#### DRUNK AND DYING.

WE frequently have to record cases of death from apoplexy or other disease in the police cell. In too many instances the unfortunate has been rudely lodged there under the supposition that it is simply a case of "dead drunk." This week we hear of a case from Aberdeen in which the prisoner was arrested with a companion as drunk and disorderly, and apparently the two women were at least very drunk. They were frequently seen through the night, but about 4.30 A.M. one of them was found on the floor dead. Dr. Macgregor was, of course, unable without a post-mortem to certify the cause of death, and when this was afterwards performed, along with Dr. Frank Ogston, pulmonary apoplexy was found to account for death. Professor Ogston states that sudden deaths often arise from this cause. This woman was about thirty years of age. In this case there was probably little to indicate the approaching danger, but where real illness is present or suspected the raised and sloping portion of the floor dignified by the name of bed is not likely to conduce to recovery.

#### ROCHDALE MANURE WORKS.

THE Rochdale system of excrement removal and disposal is about to undergo an important modification. The excreta of the population are collected separately by means of a pail-privy system, and they are then conveyed to works where they are manufactured into a manure for which a ready sale has always been obtained. But the process of manufacture is alleged to have caused nuisance, and to be somewhat expensive. Hence a new system is to be substituted for the old one, the process being one by which the contents of the pails, after admixture with chemicals to fix the ammonia, &c., will be submitted to a current of dry air at a temperature of 1200° Fahr., in revolving cylinders. The result is the almost immediate reduction of their contents to a powder, which

forms a valuable manure. The contents of ashpits constitute the only fuel required, and in this one item of fuel alone a saving of over £500 a year is expected. After a series of experiments made with the aid of the superintendent of the works, to whom the new process is due, Mr. Alderman Taylor has brought the subject under the notice of the Corporation, and their sanction has been given to the purchase of such apparatus as the Health Committee may require in effecting the desired change.

#### UNCERTIFIED CAUSES OF DEATH IN BRISTOL.

THE Medical Officer of Health for the City of Bristol, in his report for the quarter ending June last, calls attention to the number of uncertified causes of death registered within his sanitary district. It appears that during the three months under notice thirty-three uncertified causes of death were registered in Bristol, equal to 3.1 per cent. of the total deaths. Nineteen of these thirty-three deaths were attributed to premature birth; and Mr. David Davies records his opinion that a record of the primary cause of the premature birth should in such cases be ascertained and recorded. Unfortunately, the present state of registration law makes no provision for the certification of causes of death unless a registered medical practitioner has been in attendance or an inquest is held. Neither of these conditions is fulfilled in a large proportion of cases of premature birth, hence no satisfactory evidence can be forthcoming as to the true cause of death. Mr. Davies thinks that when premature birth is the cause of the death of an infant as certified by a registered medical practitioner, it is much to be desired that, whenever possible, the cause of the premature death should be stated. We fear that the true value of careful certification of causes of death from the point of view of public hygiene is not yet sufficiently recognised. More precise information as to the large proportion of infant mortality attributed to premature birth would possess a very definite value.

#### THE PONT DU PECQ MURDER.

No special medical, or even medico-psychological, interest attaches to the Pont du Pecq murder or the murderers. It seems to have been a case of consummate villainy throughout. If there be any notable feature in the affair it is the elaboration — we had almost said the refinement — of the utter scoundrelism shown by one of the delinquents. We fail to discover trace of "extenuating circumstances" in the case. The woman was, if possible, worse than the man, and the brother must have been as corrupt as, if not equally criminal with, the principals in this atrocious tragedy. It is necessary to protest against the attempt to throw a glamour of interest over crimes by treating them as of psychological interest. There is no interest in such cases; they are simply the outcome of infinitely contemptible and degraded natures, from which the stamp of humanity seems to be wholly effaced.

A VIRULENT epidemic of measles, marked by unwonted fatality, has, it is reported, broken out at Fraserburgh, a Highland village. The population almost wholly subsist by fishing, and their habitations are, as might be expected, very defective in the matter of air-space and sanitary arrangements generally.

ONE of the best maps of the seat of war in Lower Egypt which we have seen is that issued by Mr. Stanford, of Charing-cross. It is on a scale of two miles to an inch, and is admirably clear and well defined.

THE Companionship of the Order of the Bath has been conferred on Fleet Surgeon Doyle Money Shaw, Royal Navy.

DR. BARRY, who was instructed by the Local Government Board to inquire into the cause and extent of the epidemic of enteric fever at Bangor, has made a preliminary statement to the sanitary authority of that place. He arrives at the conclusion that the main cause of the outbreak, which up to last week had led to 141 attacks and 8 deaths, was pollution of the water-supply above the point of intake, but that the disease was spread by the gravely defective condition of the sewers and house-drains in respect of ventilation. In all these respects his opinion is confirmatory of that given by Dr. Rees, the local medical officer of health. Dr. Barry strongly urged remedial measures upon the authority.

THE outbreak of small-pox in Newcastle is causing considerable anxiety to the inhabitants of the town. Fortunately the sanitary authorities are in possession of a hospital to which cases may be removed, and the means of removal, in the shape of a comfortable ambulance, is provided by the Corporation. The epidemic seems to be almost entirely confined to the Byker district. In spite of energetic action on the part of the authorities, and the increased labours of the vaccination officers, the disease appears at present to give no indications of subsidence.

## HEALTH OF THE ARMY.

### No. II.

IN an average annual strength of 50,136 European soldiers serving in India, exclusive of the field force in Afghanistan, the proportion per 1000 of strength admitted into hospital was 1748, died 24·65, sent to England as invalids 29·88, and constantly non-effective from sickness 69·32. These are all lower than in 1879, but, with the exception of the invalids, considerably above the average of the last ten years. The reduction upon the results of the preceding year has been manifest in all three Presidencies except as regards the deaths in Bombay, where there has been a very marked increase.

In the Bengal Presidency the admissions were in the ratio of 1763, the deaths of 29·26, the invalids of 25·51, and the constantly sick of 70·29 per 1000. These ratios, and especially the deaths and mean sick, are very unsatisfactory compared with the average of the last ten years, although lower than in 1879. If the strength and casualties of the field force were added the death-rate would be as high as 32·68 per 1000, of which only 1·68 was caused by wounds in action. The most prevalent diseases were fevers, which gave rise to nearly half the admissions, and next to them rank diseases of the digestive system. The latter were the most fatal, though very little higher than fevers, and next to these was cholera. The Peshawar division as usual furnished the highest proportion of cases, from the prevalence of paroxysmal fevers, which were the cause of a great amount of sickness also in the Meerut, Gwalior, and Rawal Pindi divisions. The highest death-rate was in the Peshawar, and next to it, omitting troops on the march, in the Oudh division; in the former the excess was chiefly from dysentery and diarrhoea, fever and cholera, and in the latter from fever and cholera. In the appendix to the report a table is given "taken from the report of the principal medical officer," showing the deaths at each of the stations, but the sum of them when grouped in divisions differs so much from those accounted for in the classified table of diseases that it seems quite untrustworthy. For instance, in the Oudh division only 59 out of 82 are allotted to stations, in Meerut 59 out of 76, in Sirhind 38 out of 62, in Rawal Pindi 45 out of 82, and in Peshawar 96 out of 120. We cannot but think that if the table could not be corrected to at least a much nearer approximation it would have been better omitted, or some explanation of the discrepancies should have been given.

A table appended to the report shows that 278 cases of enteric fever and 94 deaths occurred in the command, ex-

clusive of 90 cases with 40 deaths in the Frontier Field Force, being in the ratio of 9·07 and 3·07 respectively. The stations at which it was most prevalent and fatal were Nowshera, Lucknow, Ranikhet, Dugshai, Bareilly, Sitapur, and Moradabad. The 30th Regiment, which had just arrived from England, had 65 cases and 13 deaths at Bareilly and Ranikhet and other stations in the Rohilcund division. In the Peshawar division the disease occurred chiefly in the 8th Hussars, 12th and 14th Regiments. No information is given as to the corps in which it prevailed in the other divisions. Nearly half of the cases occurred in the second quarter of the year. Cholera was the cause of 6·8 admissions, and 4·86 per 1000 of the strength. It prevailed in an epidemic form at Allahabad and Lucknow. At the former station the admissions were in the ratio of 57, and the deaths of 42 per 1000, and at the latter of 26·7 and 17·81 respectively. It also prevailed, though much less severely, at Cawnpore, Moradabad, and Peshawar. Among troops on the march, the average strength of which for the year was 2180, there were 41 cases and 34 deaths. With reference to the advantage derived from the immediate removal of troops from a station on the outbreak of cholera, the principal medical officer observes, "The benefits derived from leaving the infected locality have again been plainly shown, but this should be done as soon as possible, and to as great a distance as possible. 'Preparatory' camps in the neighbourhood of the infected barracks rarely produce any good effect. It would be more prudent to prepare a camp at a selected distant site as soon as the disease is reported in the city or district, and to remove the troops to it by railway at the earliest indication of disease in cantonment. The circumstances of the epidemic at Allahabad were plain as to the danger which is incurred by keeping the troops loitering about an infected locality instead of immediately removing them to a sufficient distance."

As we have already stated, diseases of the digestive system are the class which has given rise to the highest rate of mortality. In the Peshawar division the deaths by dysentery and diarrhoea amounted to 9·47 per 1000 of mean strength, and among troops on the march to 8·97. The ratio was also very high in the Meerut and Rawal Pindi divisions. It is worthy of note that there was not a single death by either of these two diseases recorded at the hill stations. There were 230 admissions and 86 deaths by sunstroke, but no information is given as to the localities where or the circumstances under which they occurred; the admissions were in the ratio of 7·50, and the deaths of 2·80 per 1000 of strength. From an examination of the tables we infer that Peshawar and Lahore furnished an undue proportion of the deaths.

The remarks by Surgeon-General Crawford—now Director General—on the sanitary conditions of the troops in Bengal, and their influence on the character of prevailing diseases, are deserving of careful study. We cannot afford space to enter upon all the points discussed, but shall confine ourselves to the following extracts on the subject of the diet of the soldier. In a memorandum by the Army Sanitary Commission it is stated "that by the experience of medical officers much of the loss from invaliding in Indian climates is due to the continued action of habits of eating, drinking, and clothing, which are directly opposed to the requirements of those climates. In every one of these points improvements can be introduced. What is wanted, in fact, is not transference to India of the European method of rationing and management, but the adoption of a rational regimen for the British soldier adapted for Indian climates; possibly more than one such regimen would be required in different districts of the country." On this Dr. Crawford remarks: "Such a proposal is extremely plausible, and no one can doubt but that if diets of large bodies of soldiers could be made more suitable to the climate, a great proportion of disease under Group IX [diseases of the digestive system] would disappear. But the practical difficulties in the way are enormous, and even supposing that six or seven such suitable diets for India, from Colombo to Peshawar and Thayetmyo, could be arranged and enforced, the possibility of reduced dietetic diseases would still remain doubtful, because it is less what the soldier eats and drinks by order which produces disease than what he eats and drinks without order. . . . And the Sanitary Commission do not state what is to be done if the soldier does not accept that view of a reduced diet. . . . The remarks of the Army Sanitary Commission do not appear to have been based on a sufficient appreciation of the fact that the main difficulty to be overcome in reducing dietetic disease in India is to

induce the soldier to be self-denying, temperate, and careful individually. So far as the regulations are concerned every forethought is given as to what he should eat and drink and what he should avoid. But considerations of health are rarely balanced against temporary enjoyment, and sickness too often follows, not from want of due care by the authorities, but, in spite of all rules, by the carelessness of the soldier himself. These are evidently the matured opinions of a man accustomed to deal practically with soldiers, as opposed to the theoretical ideas evolved in a room in the great establishment at Pall-mall.

In Madras the strength of the troops was 10,280, and the admissions into hospital were in the proportion of 1370; the deaths of 10·51, the invaliding of 23·15, and the mean sick of 62·96 per 1000. These ratios are all lower than in 1879, and those of the deaths and invaliding are considerably under the average of the last ten years. The artillery furnished the highest proportion both of admissions and deaths, the cavalry the lowest of admissions, and the infantry of deaths in the command. Paroxysmal fevers were the most prevalent diseases, and next to them diseases of the digestive system, and the latter gave rise to the highest death-rate. Of the larger stations, Bellary and Rangoon both furnished heavy sick rates, and Kamptee a high death-rate. This excessive sickness was due to the prevalence of paroxysmal fevers, and the mortality at Kamptee chiefly to enteric fever and sunstroke. Twenty-five admissions and eleven deaths by enteric fever are recorded. Of these 1 occurred at Bellary, 1 fatal case at Tayrangoon, 13 cases and 6 deaths at Secunderabad in a force of 2530 men, and 10 cases with 4 deaths among 770 men at Kamptee. The evidence with regard to the disease at Kamptee points very clearly to contaminated water-supply as the cause, and the outbreak ceased on the well being closed. No information is given as to circumstances under which the cases occurred at Secunderabad or the probable causes. Only one case of cholera, which, however, terminated fatally, occurred in the command, at Tayrangoon in British Burmah. As usual, in this Presidency, hepatitis and abscess of the liver proved the most fatal in the class of diseases of the digestive system, having been the cause of 14 out of 21 deaths.

The average strength of the troops in Bombay was 9200. The admissions into hospital were 2118, the deaths 25·10, the invaliding 51·96, and the mean sick 70·89 per 1000. The proportion of deaths was one-half higher than in 1879, but the other ratios were lower than in that year; all, however, were greatly above the average of the last ten years. The most prevailing diseases were paroxysmal fevers, the cases of which were nearly equal to the average strength, and diseases of the digestive system, which were upwards of one-fourth of it. Fevers and diseases of the digestive system were the causes of upwards of half the deaths. The admissions were excessively high at Baroda, Kurrachee, Neemuch, and Ahmednugger, and the deaths at Kurrachee, Bombay, and Ahmednugger. The unhealthiness of Kurrachee is attributed by the principal medical officer to the arrival of the 98th Regiment in September "in a weakly state, many of the men presenting symptoms of a scorbutic taint, supposed to have originated in Malta, where they had served four years, and three years previously in the West Indies; they suffered much at Kurrachee from paroxysmal and other fevers." The depot of the 66th Regiment was also stationed there during the absence of the regiment in Afghanistan, and this may have contributed to the high sick-rate. At Poona "a considerable proportion of the garrison was formed by depôts consisting of the more weakly men of regiments on field service in Afghanistan, from which also many men were sent back in bad health;" and the 1st battalion Rifle Brigade arrived at an unfavourable season during the month of October. The high rate of sickness and mortality at Bombay and Colaba is also "accounted for by the arrival of the 61st regiment from Malta at the most unfavourable period of the year." There can be no doubt that the high rates of sickness and mortality in Bombay were greatly influenced by the Afghan war, which involved the necessity for troops being brought out to India at unfavourable periods, and also for the weak and sickly men being left behind when the regiments left for service in the field. There were 53 cases with 33 deaths of enteric fever in the command, being in the ratio of 5·76 and 3·59 per 1000. The stations at which it was most prevalent were Mhow, Kurrachee, Nusseerabad, Poona, and Kirkee; and the principal medical officer states that "from all the information collected suspicion is attached to the

drinking water" as the cause of it. Half the cases and deaths occurred in the last quarter of the year. There were no cases of cholera in the command during the year. The mortality from dysentery was very high in the Sind circle, which includes the station of Kurrachee, and it was also high in the Presidency division.

There does not appear to be anything calling specially for remark in the health of the troops on board ship, except the occurrence of two cases of enteric fever in H.M.S. *Euphrates* on the voyage from Malta to Bombay, probably contracted in Malta, which suggests the possibility of a connexion with the cases which occurred in the Bombay command in the last quarter of the year.

## A NEW MEDICAL SOCIETY FOR THE WESTERN SUBURBS OF LONDON.

ON Friday afternoon, July 28th, a numerous and influentially attended meeting of medical men practising in the western districts and suburbs of London took place in the board-room of the West London Hospital, and after voting Dr. Goddard Rogers into the chair, carried a series of resolutions, the most important of which constituted a new society. This, now named the "West London Medico-Chirurgical Society," is to meet at the above-mentioned hospital on the first Friday of every month, at 8 P.M., throughout the winter, for the consideration of subjects connected with the arts and sciences of medicine, surgery, and midwifery. The annual subscription is five shillings, and there is no entrance fee. Though intended mainly for the use and advantage of local practitioners, all "medical men not practising homœopathy" are eligible for membership. The Society has been started with considerable enthusiasm, although in consequence of the near approach of the holiday season and the desire to give the council and secretaries time to prepare for next winter, the meeting was held at somewhat short notice. The Society is likely to commence with about a hundred original members. The Council are keeping the list of original members open, and the secretaries are anxious to receive applications for membership. The following officers were elected for the first year:—President: Dr. Edward Hart Vinen. Vice-Presidents: Dr. Thudichum, Mr. B. J. Vernon, Mr. Hemming, and Mr. Frederick Lawrence. Treasurer: Mr. William Bird. Council: Drs. Alderson, Picket, Goddard Rogers, Sinclair, Thompson, W. Travers, Messrs. Alderton, Barnes, Sunn, Ottley, Potter, Walker, and Willing. Secretaries: Mr. C. B. Kestley and Mr. F. F. Schacht.

The new Society has an excellent room to meet in, very conveniently placed for access by rail and omnibus, and it has already a goodly number of members; it has an able and experienced president, and the idea of it appears to have been everywhere received with great cordiality. A district which includes, besides hospitals, three magnificent Poor-law infirmaries and several dispensaries must furnish plenty of material.

## Public Health and Poor Law.

### REPORTS OF THE METROPOLITAN ASYLUMS BOARD HOSPITALS.

*Fulham Hospital.*—Mr. R. D. R. Sweeting, the medical superintendent of this hospital, reports that during 1881 the total admissions of small-pox patients were 1952, the mortality being at the rate of 7·3 per cent. amongst the vaccinated, 31·0 amongst those whose vaccination was "doubtful," and 44·3 amongst the unvaccinated. During the months of October and November cases were admitted only from the borough of Chelsea, in accordance with the terms of an injunction which was obtained against the use of the hospital for the metropolis generally. Amongst the more interesting points adverted to in the report we would note the following. As many as 120 vaccinated children under ten years of age were admitted. Only three of them were efficiently vaccinated,

but the large number suffering from small-pox before the period at which revaccination is generally deemed necessary is an important consideration in determining the proper date for that operation. Amongst the diseases admitted in mistake for small-pox, measles stands first on the list, and it is pointed out how much more difficult the diagnosis is between measles and the early stage of small-pox than between chicken-pox and small-pox. All the cases of measles sent to the hospital in error were received as small-pox, but out of thirty-two cases of chicken-pox thus sent, twenty-six were at once diagnosed and hence refused admission. Since the hospital was opened Mr. Sweeting has met with small-pox in forty-four patients after alleged revaccination, and he has reported the details of the cases to a Committee of the Epidemiological Society who are investigating this subject. One undoubted example of small-pox incubated in utero came under observation. The child was born two days after the mother's attack, and its eruption appeared on the seventh day after birth. The immunity of the staff from small-pox is adverted to, but we have recently given Mr. Sweeting's interesting information as to this as summarised in his Memorandum on Vaccination.

**Deptford Hospital.**—Dr. J. MacCombie reports that 3185 acute cases of small-pox were admitted, in addition to 1590 convalescents who were sent from other hospitals to Deptford on their way to the small-pox encampment at Darent. The mortality among the vaccinated was 7·6 per cent., that amongst those alleged to have been vaccinated, but on whom no indication of the operation could be seen, was 35·9 per cent., and that amongst the unvaccinated was 47·4 per cent. Further, dividing the vaccinated into two classes, the mortality was 3·5 per cent. amongst patients having marks covering at least one-third of a square inch, whereas it was 9·5 amongst those with imperfect marks. Dr. MacCombie finds that, given good vaccination marks, children under ten years, or even fifteen years, of age run but little risk of death from small-pox, but that given vaccination as it has hitherto been performed, the mortality steadily rises from 1 per cent. amongst those under ten years to 2·8 per cent. between ten and fourteen years, and he shows also that the protection afforded by vaccination against fatal attacks of the disease is exhausted at an earlier age in the imperfectly vaccinated than in the well vaccinated. So also his experience, as detailed, is to the effect that the highest proportion of small-pox attacks amongst the vaccinated occurs at the two periods ten to fourteen years, and fifteen to nineteen years, the proportion of attacks in these two periods being respectively 19 and 21 per cent., and he infers that the influence of primary vaccination is lost in about an equal proportion of vaccinated subjects in the five years immediately preceding and immediately following the usual age of puberty. Hence, he urges, that revaccination should, as a rule, and not only as an exception, be performed some five years before puberty. He also alleges that some persons are so susceptible to small-pox that the efficient protection afforded by revaccination may wear out in some ten years, and he states that out of 3855 vaccinated patients admitted, twenty-two were found to have been successfully revaccinated in early life. The only exceptions to the immunity of the staff from small-pox occurred in a fever nurse, whose revaccination was overlooked, and in a ward servant, whose revaccination came too late to afford protection.

**Stockwell Hospital.**—In the fever hospital there were 1223 admissions, including 955 cases of scarlet fever, 162 of enteric fever, and 68 of typhus. Into the small-pox hospital 999 cases were admitted, and Dr. Bernard gives the mortality as 6·5 per cent. amongst the vaccinated, 44·1 per cent. amongst the doubtfully vaccinated, and 40·2 amongst the unvaccinated.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns, 5283 births and 3425 deaths were registered during the week ending the 12th inst. The annual death-rate in these towns, which had been equal to 19·0, 19·6, and 20·1 per 1000 in the three preceding weeks, further rose last week to 21·1. The lowest rates in these towns last week were 11·9 in Halifax, 13·1 in Derby, and 15·4 in Plymouth. The rates in the other towns ranged upwards to 26·3 in Hull, 27·5 in Huddersfield, 28·6 in Newcastle-upon-Tyne, 29·3 in Bolton, and 31·1 in Sunderland. The deaths referred to the principal zymotic

diseases in the twenty-eight towns were 752, showing a further increase of 53 upon recent weekly numbers; 439 resulted from diarrhoea, 97 from whooping-cough, 80 from scarlet fever, 59 from measles, 45 from "fever," 24 from diphtheria, and 8 from small-pox. The lowest death-rates from these diseases occurred in Wolverhampton and Halifax, and the highest in Sunderland and Hull. Whooping-cough caused the highest death-rates in Sunderland and Preston; scarlet fever in Hull and Portsmouth; measles in Huddersfield; and "fever" in Birkenhead and Derby. Of the 25 deaths from diphtheria in the twenty-eight towns, 18 occurred in London. The fatal cases of diarrhoea in the twenty-eight towns showed a further considerable increase upon recent weekly numbers, although they were again far below the average for the season; the highest death-rates from this disease were recorded in Bolton and Leicester. Small-pox caused 4 deaths in London, 3 in Newcastle-upon-Tyne, and 1 in Nottingham. The number of small-pox patients in the metropolitan asylum hospitals, which in the fifteen preceding weeks had declined from 350 to 138, further fell to 123 on Saturday last; 19 new cases of small-pox were admitted to these hospitals during last week, against 10 and 16 in the two preceding weeks. The deaths referred to the diseases of the respiratory organs in London, which had been 157, 183, and 193 in the three previous weeks, further rose to 223 last week, and were 53 above the corrected average number in the corresponding week of the last ten years. The causes of 92, or 2·7 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Norwich, Plymouth, Derby, Birkenhead, and Cardiff; while the largest proportions of uncertified deaths occurred in Brighton, Liverpool, Salford, and Sunderland.

### HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had been 21·3 per 1000 in each of the two preceding weeks, declined to 20·1 in the week ending the 12th inst.; and was 1·2 below the mean rate last week in the twenty-eight large English towns. The deaths referred to the principal zymotic diseases in these Scotch towns were 118 last week, and showed a slight increase upon recent weekly numbers; they included 61 from diarrhoea, 14 from scarlet fever, 13 from diphtheria, 11 from measles, 11 from whooping-cough, 8 from "fever," and not one from small-pox. The death-rate from these principal zymotic diseases averaged 5·0 per 1000, and was 1·1 above the mean rate from the same diseases in the large English towns. The 61 deaths attributed to diarrhoea exceeded the number in the previous week by 5, and were 24 above the number in the corresponding week of last year; the fatality from this disease again exceeded that recorded in the English towns, the largest excess occurring in Dundee and Leith. The 14 fatal cases of scarlet fever showed a marked increase upon recent weekly numbers, and included 6 in Glasgow, 3 in Leith, and 2 both in Dundee and Aberdeen. The 13 deaths from diphtheria also showed a further increase, 9 being returned in Glasgow and 3 in Greenock. The 11 fatal cases of measles included 4 in Dundee, 4 in Leith, and 3 in Glasgow; 42 fatal cases of measles have occurred in Dundee since the beginning of July. Six of the deaths from whooping-cough occurred in Glasgow, and 2 both in Edinburgh and Perth. The 8 deaths referred to "fever," of which 6 were returned in Glasgow, were 2 fewer than those in the previous week. The deaths referred to acute diseases of the lungs in the eight towns, which had steadily declined in the four preceding weeks from 95 to 74, further fell to 71 last week, and were fewer by 16 than those attributed to the same diseases in the corresponding week of last year.

### HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 20·8 and 22·9, rose again to 21·1 in the week ending the 12th inst. During the first six weeks of the current quarter the death-rate in the city has averaged 21·0 per 1000, against 18·2 in London and 18·1 in Edinburgh. The 157 deaths in Dublin last week showed a further increase of 4 upon the low numbers of recent weeks; they included 6 which were referred to "fever," 9 to diarrhoea, and not one either to small-pox, measles, scarlet fever, diphtheria, or whooping-cough. Thus 15 deaths resulted from these principal zymotic diseases,

against 12 and 16 in the two preceding weeks; these were equal to an annual rate of 2.2 per 1000, against 3.9 in London and 2.5 in Edinburgh. The fatal cases of diarrhoea, which had been 5 and 6 in the two previous weeks, further rose to 9 last week, and exceeded the number returned in any previous week of the year. The deaths referred to different forms of "fever" (mainly enteric or typhus), which had been 3 and 7 in the two previous weeks, were 6 last week. The death-rate from "fever" considerably exceeded the average rate from the same cause in the twenty-eight large English towns. The deaths of infants corresponded with the number of the previous week, while those of elderly persons showed a considerable increase. The causes of 21, or 13 per cent., of the deaths registered in the week were uncertified.

### THE SERVICES.

Sir Robert Christison, Bart., at present Surgeon General of the N.W. Provinces, India, will be succeeded by Deputy Surgeon-General J. Walker, Bengal Medical Service.

Brigade Surgeon J. Guthrie has been appointed to officiate as Principal Medical Officer of the Oudh Division, with the temporary rank of Deputy Surgeon-General, vice Surgeon-General J. E. Clutterbuck, transferred to the Home establishment and posted to Malta.

YEOMANRY CAVALRY.—East Lothian: Surgeon David James, M.D., resigns his commission.

ENGINEER VOLUNTEERS.—1st Lancashire: Acting Surgeon Robert Arthur Henry Wood resigns his appointment.

ADMIRALTY.—Fleet Surgeon John Mockridge has been placed on the Retired List of his rank.

The following appointments have been made:—Staff Surgeon W. J. Iman, to the *Warrior*, vice Mockridge; Staff Surgeon Alexander Mitchell, to the *Dragon*, vice Hudson; Surgeon Andrew D. Peyton, to the *Cambridge*, vice Miller, appointed to the *Dee*; Surgeon Thomas D. Gimlette, to the *Seahorse*; Surgeon John G. Wray, to the *Orwell*, vice T. D. Gimlette.

## Correspondence.

"Audi alteram partem."

### WHAT HINDERS NOTIFICATION OF INFECTIOUS DISEASE.

To the Editor of THE LANCET.

SIR,—Anyone reading the letter signed "R." in your last issue, on the notification of infectious disease, with your annotation thereon, might very probably consider your remarks fairly called for, always supposing that the statements contained in "R.'s" letter accurately represented the facts of the case. Let us see, however, how far "R.'s" version of the case is really the true one, and whether his letter is calculated to lead your readers to a just appreciation of the conduct of the sanitary authority and its officers in Blackpool.

To economise space, I will deal with "R.'s" letter and your annotation conjointly.

First, then, in this borough, when the house of any poor person is invaded with infectious disease, the Corporation undertake (when it is considered advisable by the medical attendant and desired by the patients or their friends) to remove the infected person to the sanatorium at the town's expense, and maintain the patient with a relative to nurse the case, if so desired, at a trifling cost, until the sickness is over and convalescence complete; each medical man attending his own patients.

Secondly, the Corporation supply, gratuitously, disinfectants of all kinds for every purpose, including carbolic oil in scarlatinal cases, to poor persons who are unable or unwilling to procure the same for themselves.

Thirdly, as soon as the medical attendant considers the proper time has arrived, the houses are thoroughly cleansed and disinfected; all clothes and bedding are disinfected or destroyed when necessary, in the latter case compensa-

tion being made, and all the expenses of disinfection being defrayed by the Corporation.

Now, Sir, in the case referred to by "R." the patient was a young child of a poor cab driver who had just come to Blackpool, and imported the disease from a distance. As such the case was notified to me on June 16th. As customary, the first thing that was done by the sanitary inspector was to offer removal to and accommodation in the sanatorium with the consent of the medical attendant, but this was declined. Isolation being refused, the inspector, acting on my instructions, told the cab driver that as he was living in the same house with a patient suffering from scarlatina he should not ply for hire. In so instructing the inspector I believed I was removing from "R.'s" shoulders the odium which attached to such a duty, and which "R." would only be glad to escape. At the same time the inspector was instructed not to interfere in any other way with "R.'s" conduct of the case. I trusted to "R." to let me know through the inspector when the cabman might safely resume his employment.

I now come to the statement in "R.'s" letter that on the 18th, while desquamation was still proceeding, the inspector gave the cab-driver permission to ply for hire. This statement the inspector declares is absolutely untrue, and I fully believe him. The inspector never saw the man at this time. The man's wife entreated the inspector to see for himself that the child was sitting up and better, which in these parts means well; she stated that "the doctor had given over coming," that her husband never went near the child, and slept in another room, and begged that he might be allowed to "take a job," which she particularised. To all this the inspector replied that it was very soon for her husband to ply for hire, but that her own doctor should know best; he never, as stated in "R.'s" letter, "gave permission," and the cab-driver ultimately resumed work on his own responsibility. It was at this time that the inspector, believing the woman's tale that the doctor had ceased attendance, suggested cleansing and disinfecting the house, as soon as the child was well enough, and told her where she could get the disinfecting oil supplied by the Corporation in such cases. It is utterly false, and a pure invention of somebody's, to say that a prescription was left at the house by the inspector; he never did so, either by my directions or without them. With the exception of what I have stated above, the whole story is a pure fiction. The paper which the inspector showed subsequently to "R." at "R.'s" house was one in which I had written down more than a year before, the form for preparing the carbolic oil, the druggist who supplies disinfectants for the Corporation having at the time forgotten the verbal instructions I had given him long before, some time in 1879, for preparing it. This paper never after saw the light until the night of June 20th, when it was shown to "R." by the inspector, at the time he was, by my directions, making an explanation to "R." of the real facts of the case. It was after all this that the inspector ascertained that "the doctor" had not ceased attendance on the case. The conversation I have above referred to between the inspector and the child's mother was the only approach to interference on the inspector's part from beginning to end of the case, and your statement that "when the medical man called on the 20th he found the work very much taken out of his hands" is utterly untrue and groundless. I myself trusted altogether to "R.'s" conduct of the case, and believing that in endeavouring to check the dissemination of the disease I had at the time done all my duty (the case having been notified as "imported"), never went near the house. I have never seen either the cabman, or his wife, or the little patient, and I never heard until the night of the 20th that the carbolic oil had been suggested by the inspector; nor did I know until after the sanitary meeting of the 21st that the borough surveyor had offered employment to the cabman during his temporary suspension from his ordinary work, and this is the first time, to my knowledge, that such a proposal has been made.

I must now say, Sir, that I think Mr. MacDonald, the inspector, has just cause of complaint against "R.," who, in his letter to a public journal, distinctly implies a falsehood to him, choosing to believe the woman, who it is evident had strong motives for saying what the inspector alleges she did say, rather than the inspector, who could have no motive in inventing an untruth. It also appears strange to me, a reader of THE LANCET for nearly twenty years, that you should depart from your usual custom in this case, and pass such a

judgment as is contained in your annotation, on the indictment made in "R.'s" letter, before hearing both sides of the case.

Sir, the whole story is a bubble, though perhaps not quite a bubble which bursts itself: it reminds one more of one of Dr. Carver's glass balls at the Aquarium, the fiction of which it is composed being vitrified with a little truth: it requires breaking. The process of smashing up the ball is easy, but vexatious to one whose time is valuable, and can be better employed.

I will, Sir, very soon offer for your acceptance a *résumé* of the results of compulsory notification in Blackpool, and I think I can convince your readers that the Act has done great good in the borough, and has been a large factor in securing immunity from infectious disease to the vast numbers of people who visit this health-resort. At the same time I shall endeavour to show that where compulsory notification obtains the Legislature should insist that the medical officer of health should be untrammelled by private practice, and free from all the influences connected with it, which tend to curtail the efficiency of his work for the public good. This would also place him out of reach of attacks made on him through his official position, and which are based on feelings from which, it is sad to say, some members of our profession are not altogether free.

I am, Sir, yours, &c.,

LESLIE H. JONES, M.D., &c.,  
Medical Officer of Health, Blackpool.

August 14th, 1882.

I have read the above letter, written by the medical officer of health, and I am prepared to declare on oath, if necessary, that the statements contained in it are true.

(Signed) FRANCIS McDONALD,  
Inspector of Nuisances.

\* \* Our remarks were intended to apply to all cases of a kind similar to that which seemed to be set forth in the letter of our correspondent "B."—ED. L.

## "STAMPING OUT SMALL-POX."

To the Editor of THE LANCET.

SIR,—It is very natural that a gentleman who has been especially engaged in contending with an outbreak of small-pox should consider that the exertions of the staff of which he was a member had materially shortened the duration of the epidemic. Yet the facts so impartially stated by Dr. Higham Hill in your issue of the 29th ult. having reference to a recent outbreak in Sydney, New South Wales, do not clearly support such an opinion; and with regard to the estimation of the value of measures of quarantine and isolation in general you may think it worth while to point this out. Dr. Hill admits that, in the absence of compulsory registration of cases of small-pox (a want which was supplied by Act of Parliament during the seventh month of the outbreak), there were many concealed cases which formed "hot-beds of infection," and which protracted the epidemic. These cases of concealment were generally believed in Sydney to be very numerous, and the attention of the Government was drawn to their existence during the early months by a physician who is a member of the Legislative Assembly. These being the facts, then—that small-pox existed among an ill-vaccinated population, that measures of isolation were imperfectly carried out, and that the total number of cases of illness was nevertheless extremely small, although they were spread over a period of nearly eight months—if Dr. Hill's opinion that the epidemic may be fairly said to have been stamped out be accredited, it must be inferred that isolation of persons suffering from small-pox is not a measure of much value in checking the spread of the disease. But this is contrary to experience.

The contagiousness of small-pox is relative in degree to conditions which are local and constitutional. The local conditions of Sydney are—a population of about 270,000, spread over a very large area; its position on the east coast of Australia, so that the prevailing winds reach it after crossing the Pacific, while to the west is an immense extent of forest land which ends only at the great central wilderness, and whence blow very dry winds; and the position of the city itself upon the banks of a harbour of which the numerous and far-reaching arms and bays are full of very deep water, and penetrate and divide the most populous parts of it in very many directions. The air is pure and exhilarating to a degree only comparable

with mountain air, and the sunlight is constant. The constitutional conditions of its people are—constant employment, high rates of wages, reasonably numerous holidays, and such supplies of good food of all kinds as the London artisan never sees except on some such rare occasion as that of a club dinner; and the knowledge that he is an important and powerful member of the community, which, if it do not always breed content, at least gives healthy occupation to his mind.

I do not wish to undervalue the effect of the measures which Dr. Hill took an able part in carrying out under grave difficulties; but I think it due to the general question of quarantine and isolation to point out that upon the whole there are strong grounds for believing that his case does not detract from the value of those measures, as his account of it leads the reader to infer. On the contrary, the just inference is that with a perfect system of isolation, and, what is much more important, with compulsory vaccination, small-pox would not assume epidemic proportions in Sydney.

I am, Sir, yours truly,

London, August 1st, 1882. J. ASHBURTON THOMPSON, M.D.

## VACCINATION IN ENGLAND AND IN SCOTLAND.

To the Editor of THE LANCET.

SIR,—Dr. Hamilton's letter on Vaccination in Scotland deserves a reply, especially as he is of opinion that, north of the Tweed, they manage this important operation better than in England. In Scotland the limit of time allowed for vaccination is six months, in England it is three. Dr. Hamilton mentions various reasons why the longer time should be preferred; but in my opinion there are stronger reasons why the three months' limit should be adhered to. If a child should be born with constitutional syphilis, three months would be ample time in which to allow the symptoms to manifest themselves; and if at the end of that period a child looked healthy, I should have no hesitation in vaccinating it, instead of waiting for three months longer, to see if any symptoms of the disease should appear. When a child is vaccinated at the age of three months it gets over the effects of the operation before the troubles of dentition begin, which are often of themselves sufficiently severe without being complicated by vaccination. Cutaneous eruptions, convulsions, and various other ailments, are more apt to manifest themselves during dentition than at any other time; and should a child, when vaccinated about the age of six months, be seized with any of those affections, the vaccination would get blamed for it. Then, should an epidemic of small-pox break out in a locality, it would be better to be able to enforce the vaccination of all infants when three months old rather than allow them to remain unvaccinated for three months longer, during which time they would be exposed to infection. In Scotland, vaccination cannot be enforced until a child attains the age of six months. In the large English towns many persons change their place of residence so frequently, and remove to districts apart from where the infants are born, that many of them are lost, and cannot be traced by the vaccination officers. For this reason London is the worst vaccinated city in the kingdom. To extend the time of vaccination to six months would aggravate this state of matters.

The vaccination grant is an allowance by Government of 1s. a head upon each infant vaccinated at the public station. This raises the fee to 2s. 6d. a case (not too large a sum). The grant is given to encourage careful and efficient vaccination. Last year £12,000 were distributed among the public vaccinators of England, and notwithstanding Dr. Hamilton's remarks about "duty," I am inclined to think that the majority of medical men in Scotland would consider it just that a fair proportion of this sum should have been allotted to deserving public vaccinators in their country. I believe that in Scotland no vaccination fees are paid out of the rates except for the infants of those who are in receipt of parish relief. In England the public vaccination station is free to all, and I have no hesitation in affirming that infants vaccinated at the public stations are more efficiently protected against small-pox than are those vaccinated by private practitioners, who are often satisfied with one vesicle.

I am, Sir, your obedient servant,

Manchester, Aug. 7th, 1882.

T. N. O.

## "SALICYLIC SILK."

*To the Editor of THE LANCET.*

SIR,—In reference to the use of the mackintosh with the salicylic dressing, will you allow me to say that, although the mackintosh was used in the cases published by me in THE LANCET last year, it was shortly afterwards discontinued, according to Mr. McGill's original suggestion.

Yours faithfully,

WALTER H. BROWN,

Late House-Surgeon to the General Infirmary, Leeds.  
August 13th, 1882.

## SCOTTISH NOTES.

*(From our Correspondent.)*

It is announced that Dr. Macintosh, F.R.S., at present Superintendent of Murthly Asylum, Perthshire, has been appointed to the chair of Natural History at St. Andrews, rendered vacant by the translation of Dr. Alleyne Nicholson to Aberdeen. Not only the many scientific friends of Dr. Macintosh, but all interested in the welfare of St. Andrews, will rejoice at the excellent selection made by the patron, the Marquis of Ailsa. Besides the work done in zoology by Dr. Macintosh, and known to all scientists, he has at Murthly surrounded himself with a collection, in the vegetable as well as the animal world, which of itself would form a respectable museum, while his efforts to the same end, in so completely furnishing the Perth Museum, show further his enthusiasm for the subject he will now be called upon to teach.

An important motion was under discussion at the last meeting of the Aberdeen Town Council. The Lord Provost proposed, and it was unanimously agreed, that a City Improvements Bill should be proceeded with next session. He went on to detail the alterations which he thought should be embraced in the scheme, which is altogether of an extensive character. By the method mentioned many advantages from a health point of view are likely to accrue, as several of the best known rookeries will be removed that the new and necessary thoroughfares may be provided. The Links, it would appear, are now owned in part by others as well as the corporation, and it is proposed that those interests should be purchased. These valuable recreation grounds will also be more accessible if Castle-street is extended thereto as proposed, and if the other drives mentioned are formed. The excellent bathing facilities will then be more easily obtained, and these it is proposed to increase by large additions to the bathing establishment. The Bill, as foreshadowed, seems specially intended to afford better means of communication throughout the town, to meet the wants of the rapidly increasing suburban population, and to extend the city boundaries; but such demolitions are involved as will have a most wholesome influence upon the public health.

Long lists have been published as advertisements in the daily papers, recording the successes of students during the past session. When well deserved, such a stimulus is likely to be useful, but honourable mention and certificates should indicate more than medium merit, and that this is scarcely so is indicated by the fact that fifty per cent. entitles the student to a place among the distinguished ones. What excuse is offered by the unsuccessful it is difficult to surmise, but, perhaps, the mention of almost 150 names in one class so reduces the number of the disappointed that the trifling residuum needs little consideration. If fifty per cent. entitles a student to honours, the not unnatural question arises, What is the percentage necessary for a pass or for honours in the M.B. Examination?

The bathing season is this year peculiarly prolific of accidents in Scotland. As many as eight fatalities have been thus caused in one day, and the season's sacrifice promises to be very large. One would imagine that some of the sea-coast towns would find it to their advantage to provide and offer special guarantees against a form of death so common and expected as scarcely longer to deserve classification as accidental. In private establishments men are kept ready for rescue in an emergency, and the frequency with which they require to act, as well as the immunity from accident which those useful institutions enjoy, point to

stricter police regulations and the employment of good swimmers to carry these out, as likely means for the saving of life, at least in the more frequented towns and villages.

It is marvellous how little is done in Scotland to render the popular health resorts more attractive. We take our cures from change of air just as seriously as we do physic. In almost none of the watering-places have we any provision made for rational enjoyment, and such common seaside pastimes as promenade concerts, balls, &c., are scarcely known, while floating baths, aquaria, picture-galleries, and even proper boating facilities are unheard-of luxuries, except at Rothesay, where some attempts have been made to follow southern models. The variety so necessary to the convalescent or overworked is difficult to find, and the town which would energetically engage to provide fitting amusements would be amply repaid.

The public health of Brechin is so bad at present that Drs. Anderson and Lawrence have felt it their duty jointly to call the immediate attention of the authorities to the subject. They forcibly point to the laxity with which complaints as to defective drainage, suspected water, &c., are considered, and mention instances where both of these are evidently the cause of the typhoid fever so prevalent at present. As is usual in these cases, the first effect of the independent criticism is disagreement all round. The owners of the suspected well write to say that on the authority of an analytical chemist their water is pure. The chemist publishes his report, and shows that he gave but a qualified approval. The magistrates are not allowed to take a sample of water from this private source for analysis, even though one of the partners is provost of the town; and the only satisfactory action taken is with regard to the drainage, which will have immediate attention. The medical men urge that notification of infectious diseases should be enforced, and are evidently prepared to accept the duty.

Typhoid fever has also broken out in Cupar, but precautionary measures have been at once adopted against its spread.

## IRELAND.

*(From our own Correspondent.)*

THE rapid development of the medical sciences, especially physiology, has demanded an outlay at all large medical schools, so as to allow the teaching to keep up with the advances that have been made. The School of Physic of the University of Dublin, and the Medical School of the Royal College of Surgeons have had large sums expended for this purpose, and the Board of the Ledwich School of Medicine and Surgery have very wisely determined to make certain alterations and additions at their institution, so as to constitute it thoroughly efficient in every respect. Contracts have been signed and the work is now being rapidly carried on, the estimated cost being upwards of £500. It will include a physiological laboratory, a chemical laboratory capable of accommodating at least seventy students, a museum for the teaching of pathology and osteology, a lavatory supplied with hot water, spirit tanks for subjects, &c.

The annual report of the President of the Queen's College, Galway, for the session 1881-2 shows that the College has steadily progressed, and it is worthy of note that the success of the Queen's Colleges was never so marked as at the time they lost their special privileges and vested educational interests as the constituent parts of the Queen's University. The number of students in the Colleges, which was 375 in the opening session, 1849-50, and which rose to 953 in 1879-80, was increasing at a much more rapid rate during the last two sessions of the University. The number stood at 1010 in 1880-81, while the closing session 1881-2 exhibited results more satisfactory than any previously recorded, the number of students receiving instruction being 1154. One hundred and twenty-two students attended lectures during the past session in the Faculty of Medicine at the Queen's College, Galway, the highest number yet recorded.

From the twenty-fourth report of the Board of Superintendence of Dublin Hospitals, it appears that nine institutions receive grants from Parliament. The number of patients admitted during the year was 8970, which, with 798 previously in the hospitals, made a total under treatment of 9768. The deaths amounted to 452, or a mortality of

5.12 per cent. on those treated to a termination; and the total average daily number of beds occupied was 718. The income was £38,653 18s. 1d., and the expenditure £37,807 3s. 1d., the large sum of £8381 2s. 2d. for salaries of officers and wages of servants being included in the latter. There is a considerable difference in the average annual cost of a bed for maintenance in these nine institutions respectively. For example, in Cork-street Fever Hospital the cost was as high as £87 18s. 11d., while in the Westmoreland Lock it was £28 16s. 4d., and in the Incurables as low as £10 18s. 10d. It is satisfactory to learn that the apartment which is placed under the seats of the operating theatre at the Richmond Hospital, and in which autopsies were heretofore conducted, is no longer to be used for that purpose.

The state of the Recorder's Court in Dublin has long attracted attention, and last week, prior to his lordship taking his seat, a suitor, owing to the excessive heat and bad ventilation, fainted. The Recorder has on more than one occasion represented the state of Green-street Courthouse buildings to the authorities at the Castle, and these representations found their way from the Castle to the Corporation, who were the responsible parties; but with that body the matter remained a dead letter. At a meeting of the Town Council last Monday, one of the members said that nothing could be worse than the condition of the courts in question. The cells beneath were simply "pest-houses," and the sanitary and other arrangements were absolutely disgraceful. The Corporation had applied to the Government and to the Grand Jury to make the necessary alterations, and ultimately a presentment was put for £2500 to be expended in remodelling the courthouse. This was cut down to £500, and eventually thrown out by the Grand Jury. There are some who consider that a new site and an expenditure of some £50,000 will be required, as to endeavour to alter the present structure would be throwing money away.

An association has been formed for opposing the Compulsory Notification of Infectious Diseases by medical practitioners, as it has been ascertained that many, while in favour of notification in the abstract, protest against the imposition of such compulsion upon the medical attendant. It is feared also that should the Bill at present pending in the House of Commons, and specially intended for England and Wales, be adopted, it would be followed by an extension of the same law to Ireland.

The annual Report of the Local Government Board is satisfactory in reference to the considerable decrease which has taken place, as compared with the previous year, of persons receiving in-door relief. A large decrease has also occurred in the number of sick admitted to the various workhouses, and to the number suffering from fever and other contagious diseases.

At the recent examinations for the Indian Medical Service Dr. Charles, who obtained first place, was a most distinguished student of the Queen's College, Cork, gaining all the scholarships and prizes of his course, and the three exhibitions at its close. He is also a Gold Medalist of the Queen's University, graduating with first honours.

Dr. Michael Kinane of Templemore, Tipperary, died on the 11th inst., after two hours' illness. The deceased gentleman had been married only a few days.

The Rev. Dr. Egan, late President of the Killaloe Diocesan College, has been appointed a Fellow of the Royal University of Ireland.

Small-pox has disappeared from Dublin for upwards of a year, but it exists to a slight extent in Belfast and Clonmel.

**AMBULANCE CLASSES FOR THE POLICE.**—At Scotland Yard last week certificates were presented to seventy-nine police officers who had passed the examination of the St. John Ambulance Association. Dr. Sieveking presided; and there were also present—Dr. Steet, medical officer, General Post Office; Colonel F. Duncan, R.A., director of the Association; Captain H. C. Perrott, secretary; and others.

ON Saturday afternoon, the 12th inst., the remains of Dr. James Miller, of Great Percy-street, Clerkenwell, were interred in Kensal-green Cemetery. Dr. Miller, who died somewhat suddenly, had been one of the police divisional surgeons of the G or Clerkenwell division for some ten years, and the police, to show their respect, gave him a public funeral.

## PARIS.

(From our Special Correspondent.)

THE last *Compte Rendu* of the Biological Society contains the description of a new instrument presented to the Society at a recent meeting by Dr. Danillo of St. Petersburg and called the "Reflexometer." It is used for measuring the force required to obtain the phenomena known as "reflexes" or myotatic movements, as well as for indicating

the exact moment at which percussion takes place. The inventor thinks that investigation as to the changes of medullary reflectivity

under pathological conditions will be rendered more exact when its physiological variations are better known. The instrument consists of a metallic rod, fifteen centimetres long by five millimetres wide. The free extremity carries the percutor, whilst the other is movable around an horizontal axis, at the junction of a second rod parallel with the first and its handle. A glance at the figure kindly furnished by

the maker, M. Galante, will make matters clearer. Percussion is obtained by a semi-circular spring, one end of which is fixed at the junction of the rod and handle, whilst the other presses upon the rod. A segment of a circle, with a scale representing the force of the spring in grammes, is attached to the immovable part of the apparatus; while a cursor on the movable rod gives the reading. The fork on the lower branch is applied to the muscle or tendon under examination, and the percutor is raised by a little transversal bar in front of the cursor to the required height. The contact of the percutor with the tendon corresponds with the parallelism of the two rods, and with the contact of a screw on the movable branch, with the insulated binding screw of the immovable branch. This is announced by a Deprez signal worked by a battery, the rheophores of which are connected, one with the binding screw already described, and the other with a screw placed at the junction of the handle and rod. Dr. Danillo's apparatus is the modification of an instrument proposed for the purpose and described by M. Brissand in his inaugural thesis.

The same bulletin contains a communication by Professor Charles Bouchard, on the presence of ptomaines, or cadaveric alkaloids, under some circumstances, in the urine. The investigations of Bronardel and Bontney brought to light a test which shows that there is a great analogy between these alkaloids and the poisonous fungi. On the other hand, the ptomaines only appear in animal matter where microscopic vegetable organisms are found. Hence the supposition that cadaveric alkaloids are the product of dissimulation of vegetable organisms. If bacteria living in dead animal matter produce ptomaines, it is possible that the bacteria of a living animal organism may produce analogous substances. Starting from this hypothesis, Professor Bouchard submitted the urine of a number of patients to analysis, after having carefully arranged their diet, and excluded all alkaloids from their medication. In order also to prevent any fermentation or putrefaction, the urine was discharged into a recipient containing a sufficient quantity of powdered boric acid to saturate it. These researches were made in a number of cases of typhoid fever, two of infectious pneumonia, one of infectious pleurisy, and one of

icterus occurring in the course of a phthisis, and which was judged to be infectious from the coincidence of an infectious nephritis. The chemical process employed for the detection of the alkaloids invariably failed to reveal their presence in healthy urine. This is not in accordance with the results obtained by M. Pouchet, but the contradiction may be due to a difference in the mode of research. But in the infectious cases the ptomaines were always to be found. The quantity generated daily in a case of typhoid does not appear to exceed a milligramme. Whether the toxic effects of the product have any bearing upon the symptoms of the disease remains to be seen. Some experiments with hypodermic injections in rabbits and guinea-pigs were negative, in one instance only giving rise to dilatation of the pupil and acceleration of the heart's action.

In a former letter, Sept. 3rd, 1881, an account was given of a new treatment for small-pox, advocated by Dr. Ducastel before the Academy of Medicine. It consisted in the administration of a mixture containing opium and ether, of a second mixture containing perchloride of iron, of the hypodermic injection of ether, and the administration of alcohol. Since May 1st, Dr. Dreyfus-Brisac has been in charge of some small-pox wards, at the Hospital St. Antoine, where he has had a full opportunity of testing its value. His report is published in the current number of the *Gazette Hebdomadaire*. The treatment was at first carried out in its entirety, but after a time the perchloride of iron was omitted except in hæmorrhagic cases. The injections of ether were disagreeable, but not enough to cause any of the patients to refuse them. Sometimes they caused a painful inflammatory induration, which occasionally terminated in a purulent collection, requiring incision, or in a small superficial sore which heals up rapidly. The effect of the treatment on the general intoxication remains problematic, but its influence on the eruption is undeniable, and the description given by M. Ducastel is confirmed in every particular (see THE LANCET, Sept. 3rd, 1881). The papules on the mucous surfaces abort in the same way as those on the skin, and since the introduction of the treatment the necessity for gargles has almost entirely been done away with. Considered in connexion with the eruption only, small-pox is transformed into varioloid, and the serious complications of the third period of the disease scarcely ever occur; one patient only having succumbed from this cause. In many of the cases a severe eruption of boils, without any evil consequence, occurs during convalescence. Dr. Dreyfus-Brisac has always endeavoured to carry out the treatment with opium and ether, but he thinks that the former plays the more important part, for when the mixture, as occasionally happens, is rejected by the stomach, and the treatment is practically reduced to the hypodermic injection of ether, the result is far from being as satisfactory as with the mixed medication.

M. Felizet, surgeon to the Paris hospitals, believes that he can cure diabetes with bromide of potassium, and has made a communication both to the Academy of Sciences and the Academy of Medicine to this effect. He states that, having had occasion to administer this drug for nervous symptoms, occurring in a glycosuric patient, the sugar diminished coincidentally with the improvement of the nervous condition. The administration of bromide to animals suffering from experimental glycosuria (from pricking the fourth ventricle) confirmed this result; and during the last six years M. Felizet has satisfied himself of the curative effects of the remedy in no less than fifteen carefully observed cases. Bromide of potassium is mentioned in nearly all the text-books amongst the medicines useful in diabetes; and Baggie and Flint have especially studied its action in this disease. Such an extraordinary success as that described by M. Felizet is, however, quite unknown to physicians. Let us hope that the discovery of our *chirurgical confrère* may be confirmed by future experience, and that this incursion into the domain of medicine may not prove the wisdom of the old saying concerning the *sutor* and the *crepida*.

The world is indebted to M. Naquet, the celebrated chemist, politician, and advocate for divorce, for the invention of ——— a new hair dye! The *Figaro* having discovered the fact that a patent had been taken out some time since by a person of this name, propounded the question whether the inventor was really the well-known deputy. M. Naquet has replied in a witty letter explaining the circumstance. He says that he had been strongly impressed two or three years ago by the report of Dr. Dubrisay to the

*Conseil d'Hygiène*, on the poisonous composition of most hair dyes. A minister of the Empire had even lost his life in consequence of their use. Since the ridiculous practice of staining the hair exists and that satire is unable to put it down, M. Naquet thought it would be a humane enterprise to seek some harmless substitute for the dangerous compounds generally employed. The dye for which he took out a patent is a mixture of subnitrate of bismuth and hyposulphite of soda. Being unwilling that his name should be used in connexion with it, or to engage in its manufacture or sale himself, M. Naquet had intended to make over his rights to someone who should work the patent for the benefit of all but in the midst of his numerous occupations he had forgotten all about it. At the present time the patent has lapsed and the invention become common property.

Paris, August 15th, 1882.

## MEDICAL NOTES IN PARLIAMENT.

IN the House of Lords on Monday the Artisans' Dwellings Bill passed through committee and was reported without amendments to the House. The Poor-law Amendment Bill was read a third time and passed, as was also the Artisans' Dwellings Bill on Tuesday.

In the House of Commons on Thursday, the 10th inst., a return was presented, on the motion of Mr. Dodson, containing a list of the alkali and other chemical works registered under the Act of 1881.

On Friday, a petition for redress of the grievances of militia surgeons was presented from the South Midland Branch of the British Medical Association.—A copy was presented of the half-yearly report to the Lord Chancellor of Lunacy Visitors.

On Saturday, the 36th report of the Commissioners in Lunacy was presented.

On Monday, the Lords' amendment to the Commons' amendments of the Lunacy Registration Bill was agreed to.—An abstract of the accounts for 1881 of county and borough asylums was presented.—Mr. O'Donnell put a fresh series of questions to the Secretary for India with reference to the mortality in Indian gaols, and Lord Hartington again replied that the Government of India were not of opinion that it was caused by the reduced dietary, and that he saw no grounds for imputing neglect of duty to the prison officials.

On Tuesday, the 31st report on the district criminal and private lunatic asylums of Ireland was presented, as also was the annual statistical report on the health of the navy.

### Carandonagh Water-supply.

Mr. Healy gave notice that he would ask the Chief Secretary to the Lord Lieutenant of Ireland if he had any objection to lay upon the table the report of Professor Leebod's analysis of the Carandonagh waters, in the year 1875-6, for the Local Government Board; whether it is the fact that the town contains 750 inhabitants, exclusive of workhouse, hospital, military, and constabulary barracks, and that for over eleven years the water-supply has been insufficient and very bad; whether, during the same period, typhus and typhoid fever were never absent summer or winter; if two dispensary doctors have died from fever in this town; whether the present doctor immediately after his appointment suffered for many months from fever; whether many other inhabitants of the town have suffered in the same way; and whether, under all the circumstances, anything can be done by the Local Government Board to insist upon a proper supply of water being obtained.

### Surgeon M'Gann.

Mr. O'Shea gave notice of the following question to the Secretary of War:—Whether the cases of Surgeon M'Gann, and other officers of the Medical Department, whose distinguished services in South Africa were mentioned in General Orders and Despatches, have been considered.

On Wednesday, the annual report on sanitary measures in India was presented.

On Thursday, in reply to Mr. O'Shea, Mr. Childers stated that several medical officers did excellent service in the late war in South Africa, of whom Surgeon M'Gann was one.

They had been thanked for their services, and their conduct had been duly recorded.

#### *The Norwich Vaccination Inquiry.*

Mr. Dodson, in reply to Mr. Hopwood, stated that he had received a report from the medical inspector who visited Norwich with regard to the deaths which were attributed to the effects of vaccination. In consequence of that report, he had directed a public inquiry to be held; and considering the gravity of the cases, and the strong public feeling regarding them, he proposed to associate with the local inspector one of the Local Government Board's most experienced general inspectors in the conduct of the inquiry.

## Obituary.

### DR. ARTHUR G. REID, OF HANKOW, CHINA.

OUR obituary list contained a few weeks ago the announcement of Dr. Reid's death at Hankow, on June 20th, the news having been received by telegram. A widespread circle of friends in the East and at home will have learnt with much sorrow that so promising a career has been brought to a premature close. Dr. Reid was educated at the University of Edinburgh, and after having been house-surgeon to the late Professor Spence, with whom he formed ties of close friendship, settled at Hankow in China, in practice amongst the foreign residents. His professional zeal not finding sufficient scope amongst the small foreign population, he conducted gratuitously a hospital for Chinese under the auspices of the London Missionary Society; and it was in this field that he made the numerous clinical observations regarding leprosy which were published in the *China Customs Gazette*, and which are quoted in all modern standard works on that disease.

Dr. Reid recently visited Europe and enlarged his experience by visits to the hospitals of Edinburgh, London, Paris, and Vienna, keeping steadily in view the acquisition of the modern methods of investigation in diseases of the nervous system, with special reference to their application to the study of leprosy. He intended to remain only a short time in China; and the chief inducement that reconciled him to the prospect of a further stay in Hankow was the hope of being able to throw some further light on that obscure disease. We understand that Dr. Reid had accumulated extensive notes in reference to the distribution of the disease in Central China; and it is to be hoped that some means may be taken of rendering the information they contain available to the profession.

Dr. Reid died suddenly of sanguineous apoplexy, when apparently in his usual health. He was a little over forty years of age.

## Medical News.

UNIVERSITY OF LONDON. — The following is the list of candidates who have passed the recent Intermediate Examination in Medicine:—

#### FIRST DIVISION.

Anderson, George Elliott Caldwell, Guy's Hospital.  
Bowes, William Henry, Guy's Hospital.  
Brock, James Harry Ernest, University College.  
Carr, John Walter, University College.  
Elliott, John, B.Sc., Owens College and St. Barthol. Hosp.  
Hayman, William Speed, King's College.  
Innes, Charles Barclay, St. Bartholomew's Hospital.  
Jones, Fredk. Wm. Caton, St. Bartholomew's Hospital.  
Jones, Samuel Cromwell, University College.  
M'Cabe, William Alexander Bowes, University College.  
Purslow, Chas. Edwin, Queen's and Mason Colls., Birmingham.  
Spong, Charles Stuart, B.Sc., Guy's Hospital.  
Watson, William Ivens Buswell, Guy's Hospital.  
Wells, George Lee, St. Bartholomew's Hospital.  
Woolbert, Henry Robert, University College.

#### SECOND DIVISION.

Adie, Joseph Rosamond, University College.  
Andrews, Charles, University College.  
Arkle, Charles Joseph, University College.  
Barnett, Lawrence, University College.  
Bernard, Letitia Caroline, Lond. School of Medicine for Women.  
Brogden, Richard William, Guy's Hospital.  
Caldecott, Charles, Guy's Hospital.  
Chapman, Harry Cecil, St. Bartholomew's Hospital.

Cocking, William Tusting, University College.  
Cooper, Henry Charles Evans, Guy's Hospital.  
Dutt, Upendra Krishna, B.Sc., St. Mary's Hospital.  
Fenton, Herbert Alfred Hill, St. Thomas's Hospital.  
Fisher, Henry Holdrich, St. Bartholomew's Hospital.  
Flemming, Percy, University College.  
Frames, Alfred Cromwell, St. Bartholomew's Hospital.  
Francis, Alfred George, St. Bartholomew's Hospital.  
Hinds, Frank, University College.  
Hodgson, Gerald George, King's College.  
Hurst, Walter, Owens and University Colleges.  
Irvin, Frederic David, University College.  
Joberns, William, Queen's and Mason Colleges, Birmingham.  
Lanckester, Herbert Henry, St. Thomas's Hospital.  
Little, Arthur Nicholas, Bristol Medical School.  
Mumby, Langton Philip, Westminster Hospital.  
Penrose, Francis George, University College.  
Pettifer, Edmund Cleaver, St. Bartholomew's Hospital.  
Pilgrim, Herbert Wilson, University of Edinburgh.  
Randell, Reginald Maurice Henry, Guy's Hospital.  
Robinson, Henry Betham, St. Thomas's Hospital.  
Rouse, Rolla Edward, St. Thomas's Hospital.  
Sellick, James Henderson, Guy's Hospital.  
Stragnell, Walter Thomas, St. Bartholomew's Hospital.  
Swain, James, Westminster Hospital.  
Taylor, Alfred Ernest, Guy's Hospital.  
Trautman, Frank, Bristol Medical School.  
Turner, Philip Dymock, University College.  
Vernon, John James Dean, Guy's Hospital.  
Vince, John Foster, Queen's and Mason Colls., Birmingham.  
Voelcker, Arthur Francis, University College.  
Whitcombe, Philip Percival, St. Mary's Hospital.  
Williamson, Richard Thomas, Owens College.

#### EXCLUDING PHYSIOLOGY.

##### FIRST DIVISION.

Carpenter, George Alfred, St. Thomas's Hospital.

##### SECOND DIVISION.

Freeland, Freeland John, King's College.

Lanckester, Alfred Owen, St. Bartholomew's Hospital.

#### PHYSIOLOGY ONLY.

##### SECOND DIVISION.

Gross, Charles, Guy's Hospital.  
Shillito, Henry, Birmingham School and Mason College.  
Tilly, Alfred, St. Mary's Hospital.

APOTHECARIES' HALL. — The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on Aug. 10th:—

Cox, Roland Frederic, Twickenham.  
Myddelton-Gay, Edward Herbert, Littlehampton.  
Smith, James Edward, Hammersmith.  
Thomas, Arthur William, Chelsea.  
Treasure, William Beeson Crawford, Crewkerne.

The following gentlemen also on the same day passed the Primary Professional Examination:—

Harry Appleton, Charing-cross Hospital; Chas. G. Gummer, St. Bartholomew's Hospital.

GLASGOW UNIVERSITY. — In the graduation list which appeared in THE LANCET of last week, the name "Gume" should have been printed *Grime*.

MR. RICHARD AXFORD, late medical officer for the workhouse and third district of the Bridgwater Union, has received a superannuation allowance of £25 a year.

A LARGE number of cases of insolation at New York are reported, resulting from the intense heat which has characterised the last few weeks.

THE scarlet fever epidemic at Accrington is stated to be on the increase. It has been decided to close all the schools of the town.

IT is proposed to celebrate the centenary of the Hull Infirmary, with the object of enlarging, improving, and endowing the institution, and of obtaining the addition of a convalescent home in connexion with it.

ROYAL BOTANIC SOCIETY. — The forty-third anniversary meeting of this Society was held last week at the Gardens, Regent's Park, Dr. H. A. Pitman in the chair. The financial condition and other matters in connexion with the Society were described by the report as satisfactory.

THE BRITISH ASSOCIATION. — The arrangements for the fifty-second annual meeting of this Association, which is about to be held at Southampton, extending from Wednesday, the 23rd inst., to Thursday, the 31st, are now completed. The first general meeting will be held on Wednesday evening at the Victoria Skating Rink, when Sir John Lubbock will resign the chair to Dr. C. W. Siemens, and the president elect will give his inaugural address. On Thursday evening there will be a *soirée* at the Hartley Institution; on Friday evening a discourse on the "Tides," by Sir William Thomson, M.A., in the Skating Rink; on Monday evening a

discourse on "Pelagic Life," by Mr. H. N. Moseley, M.A., at the Skating Rink; on Tuesday evening a *soirée* at the Hartley Institution; and on Wednesday afternoon the concluding general meeting at the Skating Rink. The several sections will meet daily at 11 o'clock in the morning from Thursday to Tuesday, both inclusive, in various public buildings. Amongst the excursions arranged for will be one to Netley Abbey and Hospital, where a garden party is to be given by the Surgeon-General and officers of the Army Medical Department.

THE death of Dr. W. H. Cook, medical officer of the Hampstead Infirmary, affords another illustration of the risks attending medical practice. Dr. Cook fell a victim to an attack of scarlet fever contracted from a patient whom he was attending for the disease.

DISASTERS AT SEA.—A Society has at last been formed for the promotion of increased places of safety on our coasts for fishermen and mariners. It is proposed that convict labour be used in the construction of these harbours. Mr. F. Johnson, Norman-road, St. Leonards-on-Sea, is the hon. secretary.

A CENTENARIAN.—On Monday evening Mrs. Burton died at her residence, Whitecross-street, Barton-on-Humber, aged 100 years. She had lived there all her life, except a few years spent in domestic service. The old lady was born on August 1st, 1782, and therefore attained her hundredth year on the 1st inst.

BRITISH MEDICAL TEMPERANCE ASSOCIATION.—At the quarterly general meeting of the Association to be held in the rooms of the Medical Society of London, Chandos-street, Cavendish-square, on Friday (this day), at 4 P.M., Dr. G. Shearer, F.L.S. (formerly of China), will read a paper on "Recent Apologists for the Opium Trade."

SEWER VENTILATION.—At a meeting of the Works Improvement Committee, Hove, on the 22nd ult., a communication was read from Mr. Paddon, of the Brighton and Hove General Gas Company, granting permission to the Commissioners to erect a shaft inside their works at Hove to ventilate the St. Aubyn's sewer, upon their undertaking to do the work to the company's approval, to remove the pipe and restore the ground upon receiving seven days' notice, to pay the sum of 1s. per year as rent, and to keep the Company clear of all expense in connexion with the work. The committee recommended that the surveyor be directed to carry out the proposed works forthwith, at a cost not exceeding £15. The same committee also recommends that the surveyor be directed to prepare and bring up plans and estimates of the cost of carrying out the necessary works for connecting the public sewers. At their next meeting (on the 5th inst.), the surveyor produced a specification of the works necessary to be carried out for connecting the sewers, and stated that he estimated the cost of carrying out such works at the sum of £2580. The committee recommend that the plans and estimate of the cost of carrying out the necessary works for connecting the public sewers be approved, and that the Board be recommended to carry out such works by contract; the sum required for the same to be borrowed under the powers of the Public Health Act, 1875.

## Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning at the latest.

ADCOCK, HAROLD, M.R.C.S., has been appointed Medical Officer for the Corby District of the Kettering Union.  
CLAYWORTH, C. CREASY, L.R.C.P.Ed., M.R.C.S., has been appointed Resident Medical Officer to the Sydney Hospital, Australia.  
CLOUGH, MORLEY EDISON, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Hambleton District of the Droxford Union.  
DAVISON, J. T. R., M.D., C.M.Ed., has been appointed Senior Resident House-Surgeon to the Royal Southern Hospital, Liverpool, vice J. M. Chisholm, M.A., M.D.Edin., M.R.C.S., resigned.  
DENNE, T. V. DE, M.R.C.S., L.R.C.P., has been appointed Medical Officer and Public Vaccinator to the No. 2 Rowley Regis District of the Dudley Union, vice H. R. Ker, resigned.  
DURDIN, ROBT. CHAS. GARDE, L.R.C.S., L.K.Q.C.P.I., has been appointed Medical Officer for the Desford District of the Market Bosworth Union.

FITZPATRICK, M. M., M.B., C.M.Ed., has been appointed Junior Resident House-Surgeon to the Royal Southern Hospital, Liverpool, vice W. H. Irvin Sellars, M.B.Ed., M.R.C.S., promoted.  
LYON, ADAM CORBETT, M.B., C.M.Aber., has been appointed Medical Officer for the Rillington District of the Malton Union.  
MANN, JOHN DIXON, M.D., M.R.C.P., has been appointed Physician to the Salford and Pendleton Royal Hospital.  
MONTGOMERY, J. W., F.O.S., has been appointed Public Analyst for the County of Westmoreland, vice Siebold, resigned.  
O'CONNOR, BERNARD, M.D., M.R.C.P.Lond., has been appointed Physician to the Hospital for Consumption and Diseases of the Chest, Mount Vernon, Hampstead, vice Dr. Burrell, resigned.  
ROE, EDWIN HODGSON, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Cadishead District of the Barton-on-Irwell Union.  
SCHMIDT, ALFRED EDWIN, L.R.C.P.Ed., L.S.A.Lond., has been appointed Medical Officer for the Third District of the Bethnal-green Union, vice Richards, resigned.  
SELLARS, W. H. IRVIN, M.B.Edin., M.R.C.S., has been appointed Second Resident House-Surgeon to the Royal Southern Hospital, Liverpool, vice J. T. R. Davison, M.D., C.M.Edin., promoted.  
SPICER, R. H. SCANES, B.Sc.Lond., M.R.C.S., L.S.A.Lond., has been appointed Resident Medical Officer to St. Mary's Hospital.  
SPURGIN, THOMAS, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Third District of the Ongar Union, vice Potter, deceased.  
STEVENSON, RALPH DRUMMOND, M.B., C.M.Glas., has been appointed Resident Surgeon to the Daylesford Hospital, Australia.  
SYMONS, CROFT GEORGE, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Bedford District of the Hoxne Union.  
WEBB, CHARLES FRERE, F.R.C.P.Ed., M.R.C.S., has been appointed Public Analyst for the Borough of Basingstoke.

## Births, Marriages, and Deaths.

### BIRTHS.

FINZI.—On the 10th inst., at Sutherland-gardens, the wife of Dr. L. M. Finzi, M.R.C.S., L.R.C.P.Lond., of a daughter.  
HARDWICK.—On the 13th inst., at Pillar House, Needham Market, Suffolk, the wife of Fredk. S. Hardwick, M.D., of a daughter.  
HUTCHINSON.—On the 10th inst., the wife of S. J. Hutchinson, M.R.C.S. &c., of Brook-street, Grosvenor-square, and Brondesbury, N.W., of a son.  
PHILLIPS.—On the 5th inst., at Woodville, New Ferry-park, Cheshire, the wife of Edward T. M. Phillips, M.R.C.S., L.D.S., of a daughter.  
PIERREPONT.—On the 4th inst., at The Common, Ealing, the wife of Dr. E. Pierrepont, of a daughter.  
RICE.—On the 8th inst., at the Infirmary, Plumstead, the wife of George Rice, M.B., C.M., of a daughter.  
SMITH.—On the 13th inst., at George-street, Hanover-square, the wife of Eustace Smith, M.D., F.R.C.P., of a son.

### MARRIAGES.

BRISBANE—WATSON.—On the 10th inst., at the Presbyterian Church, Colebrooke-row, by the Rev. Thain Davidson, D.D., James Brisbane, M.D., of 21, Park-road, Regent's-park, to Mary Jane, eldest daughter of the late William Watson, Esq., of 30, Highbury-hill, N.  
DOCKRELL—OLDFIELD.—On the 9th inst., at St. Jude's Church, Kilmainham, Dublin, by the Rev. Thos. Mills, A.M., assisted by the Rev. T. Aldwell, Morgan Dockrell, B.A., M.B. Dub. Univ., of Old Kent-road, London, S.E., youngest son of the late Thomas Dockrell, Esq., J.P., of Monkstown, co. Dublin, to Emily, only daughter of the late Alexander Oldfield, Esq., of Nottingham, and granddaughter of the late Lieutenant Ball, R.N.  
GRAHAM—PONDER.—On the 15th inst., at St. Matthew's Church, Oakley-square, J. Campbell Graham, M.D., youngest son of the Rev. W. Graham, of Bonn, D.D., M.R.I.A., to Mary Jessie, second daughter of the late Stephen Ponder, Esq., of Canton, and Hampton, Middlesex.  
HARRIS—SMITH.—On the 8th inst., at Patterdale Church, by the Rev. W. Pattinson, M.A., Vicar, Alfred Harris, M.B. & C.M., of Dalston, son of the late Anthony Harris, of Middlesborough, to Grace Elizabeth, widow of the late C. E. Smith, M.D.

### DEATHS.

CHAVASSE.—On the 13th inst., at Duchesse-road, Edgbaston, Samuel Chavasse, M.R.C.S., late of Newhall-street, Birmingham.  
COOK.—On the 2nd inst., at Abercrombie Villas, Hampstead, William Henry Cook, M.D., aged 57.  
GILES.—On the 8th inst., at his residence, Pendreath, Torquay, Richard Giles, M.D., late of Oxford.  
TENNANT.—On the 11th inst., suddenly, at Lambert-road, Brixton, William D. Tennant, M.R.C.S., youngest son of the late Rev. Sanderson Tennant, M.A., of Kensington, aged 32.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments, and Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*We cannot prescribe, or recommend practitioners.*

*Local papers containing reports or news-paragraphs should be marked.*

*All communications relating to the editorial business of the journal must be addressed "To the Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

### HOSPITALS IN THE PUNJAB.

SURGEON-GENERAL S. C. TOWNSEND'S Report of the Punjab Dispensaries for the year 1880 shows that 181 hospitals and dispensaries were open at the commencement of the year, four new dispensaries were established and one closed, leaving 184 in operation at the close of the year. 34,729 in-door and 1,838,700 out-door patients were treated, and 3531 major and 100,803 minor operations performed; the percentages of men, women, and children treated were 64, 19.5, and 16.5. Dr. Townsend notes as the imperfections of the dispensary system: (1) Want of inspection; (2) consequent suspicion of correctness of statistics; (3) employment in some districts of hakims of very doubtful qualifications; and (4) want of system in allocation of dispensaries. These matters are engaging the attention of Government.

Mr. Moore.—Our correspondent's letter has been forwarded to the advertiser.

### "THE ABORTIVE TREATMENT OF GONORRHOEA."

To the Editor of THE LANCET.

SIR,—Since reading the able papers contributed to your pages by Mr. Watson Cheyne, I would say, relative to the abortive treatment of gonorrhoea, that I have used two-drachm doses of sandal-wood oil three and even four times a day in the prodromatory and inflammatory stages of the disease, especially in "primary cases," with well-marked results. The purulent secretion has been completely arrested within thirty to forty-eight hours, rarely continuing on to seventy-two hours. The *modus operandi* I cannot explain, but have in these followed up the cessation of the discharge for three or four days by urethral injections of chloride of zinc (preferring the liquor of the British Pharmacopoeia in the preparation of the same), as, in some instances where I omitted the injections, I found the discharge reappear on the discontinuance of the oil. I might add that by the above method of treatment the inflammatory sequences are reduced to a minimum. I do not recollect whether the remedy has ever been suggested before, but in my Indian experience I have obtained very beneficial results in the treatment of paroxysmal hæmaturia with large doses of the oil, though not so large as those suggested above.—I am, Sir, faithfully yours,

C. H. F. UNDERWOOD, L.K.Q.C.P.I., &c.

Edinburgh, August 12th, 1882.

To the Editor of THE LANCET.

SIR,—In Mr. Watson Cheyne's and Dr. Ryley's treatment of the above subject I see no mention of "hydrastin," which, from an extensive practice, I can strongly recommend. The best treatment I have found might be summed up with the following:—Internally, three minims of the oil of turpentine and one ounce of infusion of buchu, three times daily. Locally, warm-water injection, followed directly by the following: Two drachms of hydrastin Canadensis, two drachms of subnitrate of bismuth, and four drachms of glycerine, with sufficient water to make four ounces, which should be retained in the urethra as long as possible. The nitrate of silver, sulphate of zinc, &c., locally I found worse than useless, and from personal experience I should certainly never prescribe any of them.

I am, Sir, yours, &c.,

Abergeldie, August 14th, 1882.

A STUDENT.

Enquirer (Edinburgh).—Messrs. Spottiswoode's, New-street-square, London.

### BICYCLE-RIDING.

To the Editor of THE LANCET.

SIR,—I should be glad if any of your numerous correspondents would inform me if their experience justifies them in concluding that bicyclists are as a class unduly affected with rupture, and whether bicycle-riding has a pronounced tendency to produce that infirmity.

I am, Sir, yours obediently,

August 14th, 1882.

F.R.C.S.

### MEDICAL AESTHETICS.

At the banquet given at the annual meeting of the State Medical Society of Arkansas (says the New York Medical Record) there were ingenious accompaniments to the feast. At each plate was a little white roll, in appearance suggesting a surgeon's bandage, and labeled "Epicurean bandage." Upon unrolling this it was found to consist of a yard of fine gros grain silk ribbon, upon the middle third of which was printed, in red letters, the bill of fare, in the form of a prescription, in Latin phraseology, the perusal of which afforded much amusement. At each plate also lay a model of a surgeon's saw in stiff card, upon which were printed the toasts, with the names of those who were to respond to them.

Mr. McNaught does not say anything in his letter to explain that part of his views which shocked us most—the proposal that, to save the rate-payers, the unfortunate officer of health should be required to attend all infectious cases for his present salary. We are glad that he approves of the notification of disease as advocated by us.

### SUCCESSFUL PRECAUTIONARY MEASURES AGAINST PUERPERAL FEVER.

To the Editor of THE LANCET.

SIR,—Noticing a fatal case of puerperal fever directly due to scarlatina poison (recorded in last week's LANCET), I thought the following case might interest your readers.

On July 31st I was called to see the child of Mrs. M—. On arrival I found the child suffering from scarlet fever. At the same time I was requested to see an aunt of the child, who was ill, and whom I found suffering from scarlet fever also. Noticing that the mother was pregnant, and to all appearances in an advanced stage, I strongly advised the immediate removal of both the patients. The mother, however, would not hear of the child being removed, but allowed her sister to be taken to the hospital, where she remains at the present time, having had a severe attack, her throat being much affected. The child subsequently skinned very freely. On August 5th the mother was taken with labour pains, and was delivered of a child at 8 P.M., in the same room in which the child was, there being no other room in which to isolate the case. I had the woman placed between sheets impregnated with carbolic as soon as labour set in; and in place of using lard to lubricate the fingers for making examinations, carbolicised oil was employed. All the napkins used then and subsequently were saturated with the same. The case progressed favourably, no bad symptoms intervening.

I should be glad to know if any of your readers have tried the same precautions in similar cases, and if with the same results; and also whether any of them have ever had similar cases where they have taken no precautions with as favourable results, as I would like to satisfy myself that it was really the precautions taken that prevented the development of puerperal fever, and not the insusceptibility of the patient.

I am, Sir, yours, &c.,

H. G. SWORN, L.K.Q.C.P., &c.

Liverpool-road, N., August 15th, 1882.

Badynion.—The rule varies in different places; but either practice is courteous, and the courtesy should be accepted and reciprocated.

### PUERPERAL CONVULSIONS.

To the Editor of THE LANCET.

SIR,—About the year 1875—I cannot lay my hand on my notes—I treated a case of puerperal convulsions by injection of morphia with success. I had administered chloroform previously, but finding the fits recurring on ceasing to give the anæsthetic, I thought to try the hypodermic injection of morphia, which had the desired effect. I have used it since in a case in which it failed to cause more than a diminution in severity, the patient of another medical man, whom I saw rather late in consultation, dying soon after. I have administered the injections advantageously in non-puerperal convulsions.

I am, Sir, your obedient servant,

RICHARD LEIGH, M.R.C.S.,  
Assistant Medical Officer to the Liverpool Lying-in  
Hospital and Ladies' Charity.

Liverpool, August 11th, 1882.

Mrs. Annabella Russell.—We know of no source for the information desired other than the various reports of the local medical officers of health.

### MEDICAL EVIDENCE WITHOUT PAYING FOR IT.

To the Editor of THE LANCET.

SIR,—The following represents a class of cases which I believe is getting rather common now, and which I think is hardly fair to medical men. I am called up early and find the patient dead. I send a certificate to the coroner's officer, stating I had seen the man a fortnight previously, and the facts of the case, requesting to know if there is any need of an inquest. The widow comes back and says that her husband's body is removed to the mortuary, and there would be an inquest. I hear no more until I see the report in the local paper, when I find that my information to the coroner is used instead of my evidence as a witness, and thus my fee is saved to the county. Is this the way that medical coroners are expected to treat their medical brethren?

I am, Sir, yours, &c.,

Highbury, August 16th, 1882.

Geo. THOS. KEELE.

## SUMMER SANITATION.

THE New York Board of Health, which has powers granted to few such municipal bodies by legislators, appoints each year fifty physicians as sanitary inspectors, who for five weeks in July and August inspect the tenement houses of the city, report the grossest nuisances to be abated, prescribe especially for the sick children of the poor, and distribute tickets to the excursions given by the various charitable associations.

**Mr. W. B. Holderness.**—The remuneration is inadequate. Our correspondent should have had an understanding before giving evidence; but he should press his claim for two or three guineas a day more.

## "SCOTCH MEDICAL SCHOOLS."

To the Editor of THE LANCET.

SIR,—“Alpha’s” letter, which puts forward the cheapness of class and hospital fees as a subsidiary attraction to the Scottish schools, may be held to apply to the Glasgow of the past, but certainly not to the Edinburgh of the present. The total minimum of the university course is put at £107 odd in the Calendar, but this does not include practical classes, and allows only one course of dissecting. It really runs up to something like £130 or £140. The cheapest (and thereto most excellent) teaching I know of is at Leipzig, where a class of laryngoscopy costs 15s., and a full course of ophthalmoscopy and Augen-klinik £1. Board and lodging are perhaps about the same in Edinburgh as in London, but the “conditions of life” that surround the student are more comfortable. There is plenty of inducement to take walking excursions into the country; then the sea is not far off, and there are plenty of tennis-courts and an excellent, if somewhat remote, cricket-field and club. The latter is chiefly kept up by the English and colonial students, as cricket, although rooting, is not quite a national game in Scotland. Rugby, Harrow, Winchester, and Marlborough men are usually to be found in the eleven plus a contingent from Australia and Canada. Scotland may well be proud that her capital attracts students of medicine from all parts of the world to the tune of about 2000. Only a small proportion of these are Scotchmen, which is not to be wondered at when we consider what the population of Scotland is, and the fact that there are schools at Glasgow and Aberdeen. Of the university graduates of 1881 only 57 out of 123 were natives. I have met a good many foreigners in my time—Frenchmen from Mauritius, Indian natives, a Russian, a Pole, men too from our remotest colonies.

I am, Sir, yours faithfully,

BETA.

Edinburgh, August 12th, 1882.

**Enquirer.**—Both particulars are essential to be known by the purchaser. It is enough to advertise the cash receipts.

L.R.C.S.E.—No.

## "LAWN TENNIS ARM."

To the Editor of THE LANCET.

SIR,—With reference to the correspondence which has appeared in THE LANCET on the above subject, allow me to report a case which I consider almost perfectly answers the description of the injury given by Mr. Morris.

Mr. G. W.—last winter, during a very hard-fought game of racquets, suddenly after a back-handed stroke felt severe pain over the pronator radii and teres, which incapacitated him from taking further interest in the game, because, as he described it, he could not hit a single ball. There was swelling and tenderness on pressure along the course of the pronator. Cold-water bandages and subsequently soap liniment gave relief. He can now play cricket, and bat half a day without the slightest inconvenience, but if he plays lawn tennis for an hour, the muscle gets so painful and stiff that he can scarcely use his arm. As in the former there is no back-stroke, it proves pretty conclusively that the back-stroke is the cause of the injury.

Mr. W.—is a well-known cricketer, very powerfully built, and all the year round in good condition, so that I do not think the present weight of racquets or tennis-bats likely to affect him; and he informs me that he always plays with a 13 oz. one, which is comparatively light.

I am, Sir, yours faithfully,

Over Darwen, August 9th, 1882.

C. SUTCLIFFE, M.R.C.S. Eng.

## A QUERY.

To the Editor of THE LANCET.

SIR,—I fancy I have had as much experience in the treatment of children as most medical men, but at the present time I have a case that rather foils me. Could any of your correspondents suggest any treatment for it? The patient is a female child, about four years of age. I was first called to see her about four months ago. She then seemed to be suffering from torpid liver, with urticaria and enlarged tonsil on the right side. She had the usual remedies and change of air, but she still has frequent daily attacks of the nettle rash, the enlarged tonsil still remaining, and the urine about normal in quantity, but turbid, as if containing mucus. In other respects the child seems well; her appetite is good; there are no symptoms of worms; no vaginitis. I have tried all the usual remedies—the alkaline salines, cod-liver oil with tonics, also warm baths and counter-irritation over the kidneys—but up to the present the patient remains *in statu quo*.

I am, Sir, yours faithfully,

August 15th, 1882.

L.R.C.P.

## COW'S MILK DURING THE PERIOD OF RUT.

To the Editor of THE LANCET.

SIR,—Some time ago a very intelligent patient made a suggestion to me in connexion with the artificial feeding of children, which I think of some importance and worthy of consideration by my professional brethren. I was in attendance on this gentleman's child, which nearly lost its life from diarrhoea and vomiting caused, I was informed, by the administration of milk of a somewhat doubtful character. This was the third attack of stomach and bowel derangement, occurring at intervals of three weeks. It was here that the father's suggestion came in: “Is it not possible, seeing that this child has got nothing but ‘one cow’s milk,’ that the bowel complaint is due to natural changes in the milk incidental to the period of rut, which in the cow is every three weeks?” This was an aspect of the question which had never struck me before, but it is the case that when this child, after recovering from the attack in question, was put on the ordinary milk that was bought for general use in the house, it had no return of the bowel derangement.

As I have no very good opportunity for the study of this question, I should like to ask those who practice in the country whether they are aware of any facts confirmatory of my patient's suggestion. Does cow's milk really undergo any alteration in composition during the period of rut? and, if so, have they noticed any ill-effects from the use of such milk?

I am, Sir, yours sincerely,

Glasgow, August 15th, 1882.

ALEX. NAPIER.

R.—Our correspondent is entitled to his fee. A midwifery engagement binds a practitioner, and has often been recognised as a sound basis for claiming the fee.

## "BLOOD DIET."

To the Editor of THE LANCET.

SIR,—With reference to giving preparations of blood to delicate children, I have been experimenting for the last five years at the Royal Hospital for Children and Women with it. At Guy's *conversations* last October I showed a specimen of dried blood dissolved in gelatine. I have come to the conclusion, after many trials, that the best way to prepare it is the following. A given quantity of blood is collected, and, before coagulation takes place, is mixed with three-parts of water, and kept in constant movement for some time, then gradually evaporated over a water bath at a temperature not exceeding 100° F. Very great care has to be taken to prevent coagulation. When the consistence of chocolate is reached, a higher temperature may be used to perfect drying. It should be reduced to a powder in a mortar. It is like coffee, with very little taste, but with a peculiar odour. If properly prepared it should be perfectly soluble in water. I commence for a child one year old with a teaspoonful during the day.

I am, Sir, yours faithfully,

ED. O. DAY,

Assistant-Surgeon to the Royal Hospital for Children, &c.,

August 12th, 1882.

M. R.—Our correspondent will find the information he requires in our Students' Number for Sept. 10th, 1881.

## DOUBLE GINGLYMUS OF THE KNEE-JOINT.

To the Editor of THE LANCET.

SIR,—The following case I think must be a novel one, and, with your kind permission, I offer it as a small contribution.

Mrs. S.—I delivered of a healthy child three months ago, the right leg folded on the thigh in front, with the toes lying in the groin. In straightening the limb I found no difficulty until it arrived at a straight position, when there was a hitch, and some little difficulty in forcing the leg backwards. On achieving that I found the muscles strong enough to bring the limb back to the position in which I found it. There was complete absence of the patella—in fact, a hollow where it should have been.

My treatment was to contrive some means of keeping the limb in a straight position, allowing the natural movement of the joint. This I attained by having a piece of poroplastic felt shaped to the back of the thigh and also the calf, with a ginglymus joint between, allowing the required movement, with what ultimate result I am not able to say; but perhaps somebody more experienced and having met a similar case may be able to say it for me.—I am, Sir, your obedient servant,

Chelsea, August 14th, 1882.

H. FISHER, M.D.

## FEES.

To the Editor of THE LANCET.

SIR,—I was called last Sunday week by the police to see a man who was at an inn. I found him to be a lunatic, and certified to that effect, so that he might be taken away to safer quarters. On the following Tuesday I received a letter by post (which I did not get till 10 o'clock, being engaged out) from the police superintendent asking me to attend at the police-court (which is about four miles away) at 11.15 A.M. the same morning to give evidence before the magistrates against the man charged with being a lunatic at large. At great inconvenience I attended, and after giving my evidence, wrote out the usual certificate in such cases, when I was offered the fee of £1 1s., and was told the Court allowed no more, which was both for certificate and attendance there.

Now, I wish to ask if that is all the fees I can claim, for the usual fee of a lunacy certificate is £1 1s.; and in a case of assault about two months ago, before the same Court, I was allowed £1 1s. for giving my evidence there as a medical witness.—I am, Sir, yours faithfully,

August 14th, 1882.

## SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year.....£1 12 6 | Six Months .....£0 16 8

TO CHINA AND INDIA ..... One Year, 1 16 10

TO THE COLONIES AND UNITED STATES .. Ditto, 1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

## Address

ON THE

GROWTH OF OUR KNOWLEDGE OF THE  
FUNCTION OF SECRETION.DELIVERED ON AUGUST 24TH, 1882, IN THE BIOLOGICAL  
SECTION OF THE  
BRITISH ASSOCIATION.

BY ARTHUR GAMGEE, M.D., F.R.S.,

BRACKENBURY PROFESSOR OF PHYSIOLOGY IN OWENS COLLEGE,  
MANCHESTER, PRESIDENT OF THE SECTION.

WHEN the Council of the British Association did me the honour of asking me to preside over this section, it occurred to me that a suitable subject for the presidential address would be a Survey of the Growth of our Knowledge of the Function of Secretion, for no subject which has recently been the object of minute study by animal physiologists is more likely to interest all devoted to biological pursuits, however diverse. I accordingly propose to direct your attention for the greater part of the time at our disposal to-day to what appears to me to be the most important and the most interesting of the researches bearing on this subject.

Before, however, entering upon the proper subject of this address, it would ill become me, as president of this section, were I not to speak to you, however imperfectly, of two great losses which we have sustained, and which have saddened, and still sadden, the hearts of many of us. The year 1882 will long be memorable, and sadly memorable, as a year during which English biology sustained irreparable losses. So much has lately been written concerning that veteran in science, Charles Darwin, who will figure in the history of the human intellect with such men as Socrates and Newton, that I feel no words of mine are needed to add to your sentiments of admiration and respect. He has made for himself an imperishable reputation as one of the subtlest, most patient, and most truthful observers of natural phenomena. His powers as an observer were, however, almost surpassed by his ingenuity as a reasoner, and his power to frame the hypothesis most apt, in the actual state of science, to reconcile all the facts which came within the range of his observation. We remember the time when the name of Charles Darwin, and the mention of the theories connected with his name awakened, on the part of many, sentiments of antagonism and of unreasonable opposition. But we have lived to witness what I may term a great reparation. Even those who did not know the man, and the qualities of mind and heart which endeared him to so many, have come to recognise that in his work he was actuated by a single-hearted desire to discover the truth; and, after calm reflection, they have conceded that his studies and his views, like all studies and all views which are based upon the truth, not only are not irreconcilable with, but add to our conceptions of, the dignity and glory of God. And here I may be allowed to remark that it is impossible to study the writings of Darwin, and especially the one in which he treats of "The Descent of Man," without recognising an undercurrent of reverent sentiment, which in one or two places finds expression in words telling us that man differs from the animal creation, if not in physical characteristics which cannot be bridged over, at least in moral attributes and in the "ennobling belief in God," by his power of forming that conception of the Deity which, to use Darwin's own words, is "the grand idea of God hating sin and loving righteousness."<sup>1</sup>

We cannot help mourning for our great ones, though they be taken from us in the fulness of years, and when their labours have been so numerous and so productive that we marvel that they have been able to achieve so much within the span of a single life; but our grief is immeasurably greater when the man of genius is taken from us in the plen-

tude of strength, as it were upon the threshold of a life full of extraordinary promise.

Francis Maitland Balfour, whose sudden death has so recently cast a gloom over us all, was a man who appeared destined to advance our knowledge of animal development more than it had been advanced by the labours of any one of his predecessors. His death recalls the train of thought which we have pursued when reflecting upon the lives and work of such men as Mayow and Bichat, Gerhardt and Clifford. If so much could be achieved in so short a life what great benefits would science not have derived, what remarkable steps in advance might not have been made, had it been given to these great minds to work on for the good of their race during a lifetime of ordinary length? It must be sufficient for us that it was destined otherwise; and, in mourning for our departed friend, we may at least reflect that we would not have had him less worthy of our admiration in order that we might mourn him the less.

## THE RESEARCHES OF FRANCIS MAITLAND BALFOUR.

At the risk of having to be somewhat brief in my discussion of the subject proper of this address, I must yield to the impulse which leads me to give you some account of Balfour's work.<sup>2</sup>

Having been educated at Harrow, Balfour entered Trinity College, Cambridge, in the year 1870. His friend and master, Michael Foster, has told us how, from the very first, besides engaging in systematic studies which he was able to pursue with no small degree of success, he devoted himself with passion to original research. At the very outset Balfour engaged in work which led to speculations of a fundamental and far-reaching nature, and of the three embryological papers<sup>3</sup> which he wrote before taking his degrees, two related to questions which occupied his attention in a special manner to the end. One of these, "On the Development and Growth of the Layers of the Blastoderm," contains several statements not afterwards maintained; for instance, as to the independent origin of the mesoblast in the chick, where it is said "neither to originate from the epiblast nor from the hypoblast, but to be formed coincidentally with the latter, out of apparently similar segmentation cells." The other, "On the Disappearance of the Primitive Groove in the Chick," calls attention to, and corroborates Dursy's discovery of seven years before, and closes with a suggestion of the great hypothesis (afterwards elaborated) that the primitive streak is a lingering remnant of the blastopore. Balfour also wrote, whilst an undergraduate, "On the Development of the Bloodvessels in the Chick," but it may be doubted whether he advanced our knowledge of this obscure subject.

The "Elements of Embryology," by Michael Foster and Balfour, appeared (1874) shortly after Balfour had taken his degree (1873), and Foster has generously recorded how great was the part his pupil took in the production of this book. The month after taking his degree he made his first journey to Naples, and it was whilst working there that he entered upon his remarkable investigation on the development of Elasmobranchs. The natural outcome of Gegenbauer's exposition<sup>4</sup> of the primitive character of this group was that increased interest should attach to all researches on its embryology. To an introductory account of the embryology of Elasmobranchs<sup>5</sup> Balfour owed, I believe, his fellowship at Trinity College, and from that time onwards until 1878 he pursued the investigation at Naples and in Cambridge. The collected results appeared in 1878, as "A Monograph on the Development of Elasmobranch Fishes." No research upon a limited group ever contained more numerous or more wide generalisations, extending over the whole domain of vertebrate embryology. I may dwell for a few moments upon some of its most interesting sections.

The structures, which we are now familiar with as "head-cavities," are described for the first time and named; their relation to the cranial nerves and their resemblance or equivalence to the muscle plates of the body is pointed out; and Balfour seizes upon their value in throwing light upon the great problems of the segmentation of the head and the segmental value of the cranial nerves. In particular the fifth nerve and the seventh, with the auditory, are

specified as the segmental nerves of the mandibular and hyoid segments. The short, but very important, notice of the sympathetic system<sup>6</sup> showed that its ganglia developed on branches of the spinal nerves, and that it was therefore a product of the epiblast.<sup>6</sup> The primitive features of the mesoblast and notochord and their hypoblastic origin are described,<sup>7</sup> and furnish material for the comparison afterwards instituted in the "Comparative Embryology"<sup>8</sup> between their development in Elasmobranchs and their still more primitive origin in *Amphioxus*, as diverticula of the archenteron. A very able chapter on excretory organs concludes this monograph. This subject had engaged Balfour's attention very early, and his introductory account of Elasmobranch Development contains his discovery of segmental organs in Elasmobranchs—a discovery made independently but simultaneously by Professor Semper. These organs are shown to develop in the mesoblast, and are compared with the segmental organs of annelids.

A paper published in 1876 gives a singularly clear and thorough résumé of our knowledge of the development of the urino-genital system; and the diagrams there given, illustrating the homologies of the male and female urino-genital organs, are wonderfully simple and instructive. Shortly after the publication of this paper, Balfour became a Fellow of the Royal Society, from which he received a Royal Medal in 1881.

Among the interesting points that Balfour had made clear in connexion with the spinal nerves of Elasmobranchs, was the fact that the anterior and posterior roots arise alternately, and not in the same vertical plane. He sought for an explanation of this in *Amphioxus* at Naples, in 1876. Owsjannikow and Stieda had discovered that the nerves of the opposite sides in *Amphioxus* arise alternately, and Stieda further stated that the nerves of the same side arise alternately from the dorsal and ventral corners of the cord. Stieda considered that two adjacent nerves were together equivalent to a single spinal nerve of higher vertebrates. Balfour<sup>9</sup> found no trace of difference of level in the origin of nerves on the same side—i.e., he denied the existence of ventral or anterior roots; and afterwards, in investigating the cranial nerves of higher vertebrates, and being unable to find any trace of anterior roots, he framed the bold hypothesis<sup>10</sup> that the head and trunk had been differentiated from each other at a time when mixed motor and sensory posterior roots were the only roots present, and that cranial and spinal nerves had been independently evolved from a common ground-plan.

Balfour's investigation of the development of the ovary was incomplete when his work on Elasmobranchs appeared; and he continued to work at this subject, both in Elasmobranchs and Mammals, publishing upon it in 1878.<sup>11</sup> A paper published in the same year on the "Maturation and Impregnation of the Ovum," contained the very ingenious suggestion that the casting out of the polar bodies prevents the ovum developing by itself into a new individual—i.e., prevents parthenogenesis; and Balfour points out that parthenogenesis is practically confined to the arthropoda and rotifers, which are the only two groups in which polar bodies are not known to occur.

Balfour still continued, now in conjunction with Sedgwick, his researches on the urino-genital system, and described, among many other new points, the existence of a head-kidney (pronephros) in the chick.<sup>12</sup> In this year, Balfour also investigated<sup>13</sup> the early development of *Lacerta*, and pointed out the presence of a primitive streak and of a neurenteric canal. This investigation confirmed his belief in the hypothesis previously quoted that the primitive streak is the relic of a blastopore.

At this time Balfour was working hard at his text-book of "Comparative Embryology." His published papers were no less numerous than before, but consisted in part of extracts from the more speculative chapters of the forthcoming book. He, however, published a paper<sup>14</sup> containing the results of work scattered over two years, on the development of Spiders. He also published a paper<sup>15</sup> on the "Skeleton of the paired

Fins," based upon his work on "Elasmobranchs." In this he contests the views of Gegenbauer and Huxley, that the primitive fin consists of a central multi-segmented axis with many lateral rays, and is most nearly retained in *Ceratodus*; he rather considers the primitive form to be a longitudinal bar running along the base of the fin (basipterygium), and giving off at right angles series of rays which pass into the fin. He adheres to the view expressed in the "Elasmobranch Fishes" (p. 101) that the vertebrate limbs are remnants of two continuous lateral fins.

Another important paper of the same year dealt with the placenta. Balfour supposed that in the primitive placentalia, simple foetal villi, like those of the pig, projected from the discoidal allantoic region of the chorion into uterine crypts. The decidual discoidal placenta of rodents and insectivores is the first stage in advance of this primitive type. Then along different lines diverge the zonary placenta of carnivora, and the diffuse placenta of suidæ, lemuringæ, &c.; and the latter contracted down to the discoidal placenta of man, a form in no way to be confounded with the primitive discoidal placenta of rodents.

He engaged also, in conjunction with Mr. William N. Parker, in a very important research, to be published in full in the "Philosophical Transactions," on the "Structure and Development of Lepidosteus." This paper contains an immense amount of new matter, both anatomical and embryological, and shows that *Lepidosteus*, though a true ganoid, has very marked teleostean affinities.

Balfour's last published paper,<sup>16</sup> which appeared during his recent illness, was written with the assistance of Mr. Deighton, and related to the germinal layers of the chick. This paper describes, in a very beautiful way, the double origin of the mesoblast, partly from an axial strip of epiblast in the line of the primitive streak, and partly as two lateral plates differentiated from the hypoblast in front of the primitive streak.

Before his last fatal journey Mr. Balfour was engaged in preparing a new edition of the "Elements of Embryology," and in producing a very elaborate memoir on the "Anatomy and Development of Peripatus." He had previously investigated that animal in 1879, and had cleared up the matter of its segmental organs (overlooked by Moseley), and demonstrated the presence of ganglia on its ventral nerve-cords.

Mr. Balfour became a member of this Association in 1871, the year after he entered Trinity College. At the brilliant Belfast meeting in 1874 he read his first paper before the Association on Elasmobranch Fishes; and this paper and Balfour's share in the keen discussion which followed are still remembered with admiration by many. In 1880, at Swansea, he delivered an address, as chairman of the sub-section of anatomy and physiology, dealing with the mutual services rendered by the evolution theory to embryology, and by embryology to the evolution theory, with special reference to the developmental history of the nervous system.

But the great text-book of comparative embryology<sup>17</sup> is the real monument of Balfour's fame. It is impossible to convey an idea of the merits of this book. It grappled with the enormous mass of scattered literature upon the subject, and formed it all into a consecutive account, clear and accurate. Discordant statements were weighed and estimated, frequently brought into harmony by an ingenious explanation or by a new and crucial observation. Countless investigations were repeated and verified, and countless suggestions of important work that still remains to be done, make the book as valuable to the student as to the student. Among the chapters<sup>18</sup> most remarkable for broad and philosophic generalisations are those dealing with the "Ancestral Form of the Chordata," "Larval Forms," and the "Origin and Homologies of the Germinal Layers." Balfour accepts the gastrula as a stage in the evolution of the metazoa, and leans somewhat to invagination, as the more primitive process than delamination in the production of the gastrula. He shows distinctly that the mesoblast arose in the first instance not independently, but as a differentiation from the other two layers, and that the mesoblast is a homologous structure throughout the triploblastic metazoa. In the chapter on "Larval Forms" he gives numerous reasons and arguments for a larval development repeating the ancestral history, better and more fully than a foetal development; he reviews the types of larvæ (discriminating

six types), the causes tending to produce secondary changes in larvæ, and suggests as a hypothesis for the passage from the radial to the bilateral type, that in a pilidium-like larva the oral face elongated unequally, an anterior part forming a præ-oral lobe, and a posterior outgrowth the trunk, while the aboral surface became the dorsal surface. He suggests that adult Echinodermata have retained, and not secondarily acquired, their radial symmetry, and considers a radially symmetrical organism, like a medusa, as the prototype of all the larval forms above the coelenterates. Balfour does not admit the specially close relationship of the Chordata with the Chætopoda, which Dohrn and Semper maintain, but considers that the Chordata descended from a stock of segmented worms derived from the same unsegmented types as the Chætopoda, but in which two lateral nerve-cords like those of the nemertines coalesced dorsally instead of ventrally. He considers that the mouth in ancestral Chordata was suctorial, and was not formed, as Dohrn supposes, by the coalescence of two visceral clefts. Finally, Balfour draws up a scheme of the phylogeny of the Chordata, according to which the hypothetical protochordata, with a notochord, a suctorial mouth, and very numerous gill-slits, acquired one by one, vertebræ, jaws, an air-bladder, a pentadactyl limb, an amnion: each new accession characterising a hypothetical protogroup, from which some existing group is supposed to have diverged.

Those of my hearers who had not followed Balfour's scientific labours, but who merely knew him as one of the most respected workers in the field of biology, will I trust, even from my brief sketch, have formed some idea of the activity and originality of his mind, and will understand how his death has occasioned a feeling almost akin to despair, in that he occupied a place which appears to us now impossible to fill.

#### ON THE GROWTH OF OUR KNOWLEDGE OF THE PROCESS OF SECRETION IN THE ANIMAL KINGDOM.

*The Views of the Ancients.*—It was known to the ancients that organs of the body exist which are concerned in the separation from it of excrementitious substances, although the greatest doubts prevailed as to the organs to which such functions should be ascribed. Thus we find Hippocrates defining it as characteristic of glands that they occur in moist parts of the body; but showing his ignorance of the true relations of glands to secretion by connecting them with the formation of hairs, and discussing the question which we find our own Wharton debating again in the seventeenth century, and which he formulates, "Num cerebrum ad glandularum numerum vel viscerum accedat." The general opinion of the ancients, and the opinion which was adopted and taught by Galen, was that the glands were sieves or collanders (cola), which served to strain off from the blood purely excrementitious substances. The liver and the kidneys were strangely enough removed from the group of glands and placed amongst the viscera. The first writer who appears systematically to have treated of the glands was the before-mentioned Wharton in his "*Adenographia sive glandularum totius corporis descriptio*." Although this author certainly added to the existing knowledge of the descriptive anatomy of secreting organs, his views on the functions of glands were strangely fanciful and erroneous.

The glands he considered to be specially related to the nervous system, the viscera, so-called, to the bloodvessels; such glands as the pancreas, and the salivary and lacrymal glands, being engaged in separating excrementitious substances from the nervous system. It was in 1665 that the great anatomist Malpighi<sup>19</sup> first attempted to investigate the structure of glands in a truly scientific spirit, endeavouring to establish a relationship between simple glandular follicles and such complex glands as the liver. All glands he believed to contain as ultimate elements bodies which he termed "*acini*," a word which in its primitive classical sense had been used to designate the stone or seed of the grape or the grape itself. The conception, indeed, which Malpighi formed of an "*acinus*" was rather that of a secreting nodule than of an ultimate saccular or tubular recess. The "*acini*," however, he believed to be in communication with the efferent ducts of the glands to which they belonged, and through which they poured out their proper secretion, derived in the first instance from the blood contained in minute arteries supplied to the gland. Ruysch (1696) known as the first celebrated injector of bloodvessels,

finding that frequently the fluids which he forced into the bloodvessels of glands escaped through their ducts, or made their way into the surrounding tissues, concluded that the bloodvessels communicated directly with the interior of the glands; these he held to be organs which, according to the views that had long prevailed, merely strained off from the blood certain of its more liquid constituents. The views entertained by the most eminent of the supporters of Ruysch, the illustrious Haller, were expressed by him as follows. After defining the term "*acinus*" to signify the ultimate division of a gland, he remarks that "*the acini consist of congeries of vessels, bound firmly together with a cellular web, containing an excretory duct in their interior, which commences from the most minute arteries by small ducts impervious to the blood. . . . So that secretion differs from the ordinary circulation of the blood in this particular, that the smallest arteries are continuous with veins of equal or greater size, capable therefore of receiving the blood, whilst the excretory ducts are much smaller, in order to effect the separation of the secretion.*"<sup>20</sup> The advocates of the Ruyschian theory were compelled to have recourse to the most improbable hypotheses to explain the diversity of the secretions of different glands: as, for example, that different glands secrete different liquids, because of the difference in the diameters of the pores by which the bloodvessels communicate with the glands; that the different arrangement of bloodvessels, the mode in which they divide, the resistance which they offer to the flow of blood through them, by modifying the pressure and velocity of the blood-flow through the organ, induce secretions varying in character. It is strange to learn from Haller, as was indubitably the fact, that the great majority of his contemporaries, such men as Peyer and Vieussens, and even Boerhaave, adopted the Ruyschian view of the structure of the glands. The opposition to Ruysch came first from Ferrein,<sup>21</sup> who maintained that the kidneys essentially consist of an assemblage of convoluted tubes, which he looked upon to be the seat of the renal secretion—tubes which a subsequent investigator, Schumlanisky,<sup>22</sup> looked upon as taking their origin in the acini of Malpighi, to which he referred the active part in secretion. Then followed the researches of Mascagni and Cruickshank, who found, by injecting quicksilver into the mammary glands, that the ramification of the ducts of this organ terminate in racemose follicles; though Mascagni still admitted a connexion, by means of open pores, between the sides of the glandular bloodvessels and the interior of the glands themselves. It was unquestionably Professor E. H. Weber, of Leipzig, who completely demolished the Ruyschian hypothesis, and who by numerous researches on the salivary glands of birds and of mammals, and on the pancreas of birds, established the general fact of the termination of gland ducts in blind extremities, though with modesty he put forward his opinions as confirming the inductions of Malpighi, expressing himself as follows:—"Admirably did Malpighi avail himself of the structure of the liver in the lower animals, and to the embryo of the higher, as a foundation stone for his opinions; for the arrangement of the whole glandular system speaks for itself, inasmuch as it simply consists of single, compact, hollow, blind canals, more or less numerous, floating in the fluid which surrounds their organs; and, although these ramifications are drawn out between the branches of the bloodvessels, there is no immediate passage from one to the other."

#### THE RESEARCHES OF JOHANNES MÜLLER.

Such was the state of knowledge in reference to the structure of secreting glands and secretion at the time when the great Johannes Müller undertook the investigation of which the results were first of all published in the memorable work entitled "*De Glandularum secretum Structurâ penitiori earumque prima Formatione*."<sup>23</sup> It is impossible not to sympathise with the reflection of Professor Heidenhain, recently made in reviewing the researches of Johannes Müller in connexion with this subject; "<sup>24</sup> to wit, that the physiologists of to-day may be accused of ingratitude for having allowed the great name of Johannes Müller to have well-nigh disappeared from the pages of physiological literature. We forget that this man—this giant in the field

<sup>19</sup> Haller, p. 275.

of biology as he is appropriately termed by Heidenhain, the last man of whom perhaps it will ever be said that he was at once the greatest comparative anatomist of his time and the most philosophical and original of all contemporary physiological writers—by his own researches, and particularly by the one which concerns us to-day, influenced the progress of physiology, at a most critical period, more than any other man. He was not, like his contemporaries Magendie and Flourens, a great physiological experimenter, though he showed that he well appreciated the value of experiment in advancing our science; but he was pre-eminently a physiologist who recognised the immense importance of a close study of structure, not only because of the interest which it presents to the pure and philosophical morphologist, but because of its absolute necessity, if we are to penetrate at all deeply into the secrets of animal function. Müller, in the first instance, had convinced himself, by the study of the circulation of organs sufficiently transparent to permit of it, especially the circulation through the liver of larval salamanders, that, in glands, arteries never end in any other mode than by capillaries leading into veins. He set himself then to study in the case of most glands, and in a large variety of animals, the relationship of gland ducts to the truly secreting parts of the organ, and the relation of the bloodvessels to these. Basing himself upon these anatomical studies of adult organs, and upon a careful study of the development of glands—a study which had been attempted slightly by Malpighi, and more satisfactorily in the case of the parotid by E. H. Weber<sup>25</sup>—Müller came to the conclusion that all glands possessed of a duct are only involutions more or less complex of membranes, the largest number being involutions of the external investment of the body or of the membranes opening upon its surface. The following are the general results relative to the structure of glands which Müller deduced from the anatomical study of individual organs<sup>26</sup> :—

1. However various the forms of their elementary parts, all secreting glands without exception (not only those of the human body, but all met with in the animal kingdom) follow the same law of conformation, and constitute an uninterrupted series from the simplest follicle to the most complex gland.

2. No line of demarcation can be drawn between the secreting organs of invertebrata and those of vertebrate animals; not merely do we meet with the simplest sacs and tubular secreting organs, like those of insects, in the higher animals, but there is a gradual transition from these simple secreting organs to the glands of the most perfect vertebrata.

3. All glands agree in affording by their interior a large surface for secretion. The varieties of internal surface by which the great end—extent of surface in a small space—is attained, are very numerous.

4. Acini, in the hypothetical sense in which the term has been used by writers—in the sense, viz., of secreting granules—do not really exist; there are no glomeruli of bloodvessels with ducts arising from them in a mysterious way, as has been supposed, whatever notions may have been held regarding them.

5. The parts described as acini are merely masses formed by the agglomeration of the extremities of the secreting canals; frequently, indeed, they are formed of minute vesicles aggregated together in grape-like bunches, which may be injected with mercury, and are often susceptible of inflation.

6. In many glands which have been incorrectly described to have acini or secreting granules, there are not even the hollow vesicular acini; the secreting tubes, instead of terminating in vesicles or cells, form long convoluted canals or straight tubuli or short cæca.

7. It has been demonstrated in the case of all glands that the bloodvessels are not continuous with the secreting tubes—that the minute vessels bear the same relation to the coats of the hollow secreting canals, and their closed extremities, as to any other delicate secreting membrane, such as, for example, the mucous membrane of pulmonary air cells.

8. The arborescent ramification of the bloodvessels accompany the ducts in their development, and the reticulated

capillaries in which the bloodvessels terminate are extended over all the closed elementary parts of the gland and supply them with blood. In the chick we may observe the simultaneous development of the two systems; in proportion as the development of internal surface from a plain membrane to cæcum and ramified cæca proceeds, the vascular layer of the originally simple membrane is raised on the exterior of the efflorescence.

9. The ramified canals and tubes, which when the structure is simple, as in insects and crustacea, and even in some glands of the mammalia, lie free and unconnected, become more aggregated together, and acquire a common covering, in proportion as their evolution is carried further; and thus is produced a parenchyma or solid organ.

10. The capillary bloodvessels are for the most part much more minute than the smallest branches of the ducts of secreting canals and their caecal extremities, even in the most complex glandular organs. The elementary parts of glands, though minute, are of such a size that the capillary bloodvessels form around them a network which invests them.

11. The formation of the glands in the embryo displays the same progressive evolution from the simple to the complex state as is observed in ascending the animal scale. The most perfect and complex glands of the higher animals, when they first appear in the embryo of these animals consist merely of the free efferent ducts without any branches, and in that state exactly resemble the secreting organs of the lower animals. The glands are formed from the unbranched tubes by a kind of efflorescence or ramification.

12. The mode in which the extent of internal secreting surface of a gland is realised is very various; and no one kind of conformation is peculiar to any kind of gland. Perfectly different glands may have a similar elementary structure, as is the case, for instance, with the testes and the cortical substance of the kidneys. And similar glands have often a perfectly different structure in different animals; of which the lacrymal glands, examined in the chelonia, birds, and mammalia, afford an example.

Johannes Müller recognised thoroughly, as we have seen, that the character of a secretion cannot be deduced from the structure of the organ which produces it. Was he able to throw any light upon the mystery which had baffled all his predecessors, and to explain the cause of the specific endowments of the different glandular organs? Let us allow Müller to speak :—"The peculiarity of secretions does not depend on the internal conformation of the glands; for, as I have sufficiently demonstrated, each secretion is in different animals the product of the most various glandular structures, and very different fluids are secreted by glands of similar organisation. The nature of the secretion depends therefore solely on the peculiar vital properties of the organic substance which forms the secreting canals, and which may remain the same, however different the conformation of the secreting cavities may be; while it may vary extremely although the form of the canal or ducts remain the same." It was the living lining substance of the gland which, according to Johannes Müller, formed the secretion, at the expense of materials which it obtained from the blood of contiguous capillaries. This living substance lining the inner recesses of the glands had not yet been differentiated into its constituent units, the secreting cells, and therefore Müller's statement wanted a certain definiteness, though, so far as he went, he was perfectly accurate.

#### THE RESEARCHES OF JOHN GOODSIR.

The success with which that eminent pupil of Johannes Müller, Theodore Schwann, had extended the generalisations of Schleiden (on the part taken by the cell in the formation of vegetable structures) to the elucidation of the animal tissues, had given the greatest impulse to the study of animal histology, and a large number of observers, especially in Germany and England, were directing their attention to the discovery and study, in all tissues and organs, of the all-important cells.

Purkinje had announced the hypothesis that the nucleated epithelium which he discovered to line the gland ducts might exercise secreting functions. Henle had described with great minuteness the epithelium cells which line the ducts of the principal glands and follicles, and which form the most superficial structures of mucous membrane, and Schwann had suggested that this epithelium probably played a part in the act of secretion. It was, however, unquestionably the Scottish anatomist, John Goodsir, to whom was

<sup>25</sup> E. H. Weber, Beobachtungen über die Structur einiger conglomerirten und einfachen Drüsen und ihre erste Entwicklung. Meckel's Archiv for 1827, p. 274.

<sup>26</sup> This abstract of Müller's general conclusions has been abbreviated from the sections treating on this subject in his Elements of Physiology. See Translation by Dr. Baly, London, 1833, vol. 1, p. 456, et seq.

reserved the merit of establishing in an indisputable manner the fact that the essential and ultimate secreting structures in glands are the morphological units, the gland cells. As Johannes Müller had examined the arrangements and coarser structure of glands throughout the animal kingdom, with the result of discovering the general plan of gland-structure, and the analogies existing between glands, however diverse, so John Goodsir passed under review the histological characters of the cells of different glands in a large variety of animals, vertebrate and invertebrate. His first results were published in the Transactions of the Royal Society of Edinburgh for the year 1842; his more matured views were developed in a paper entitled "On Secreting Structures," which formed one of a collection of papers which saw the light in 1845. As a result of his survey Goodsir came to conclusions of which the most important may be stated, almost in his own words, as follows:—"The ultimate secreting structure is the primitive cell endowed with a peculiar organic agency, according to the secretion it is destined to produce. I shall henceforward name it the primary secreting cell. Each primary secreting cell is endowed with its own peculiar property, according to the organ in which it is situated. In the liver it secretes bile, in the mamma milk, &c. The primary secreting cells of some glands have merely to separate, from the nutritive medium, a greater or less number of matters already existing in it. Other primary secreting cells are endowed with the more exalted property of elaborating, from the nutritive medium, matters which do not exist in it. The discovery of the secreting agency of the primitive cell does not remove the principal mystery in which the function has always been involved. One cell secretes bile, another milk; yet the one cell does not differ more in structure than the other, than the lining membrane of the duct of one gland from the lining membrane of the duct of another. The general fact, however, that the primitive cell is the ultimate secreting structure is of great value in physiological science, inasmuch as it connects secretion with growth, as phenomena regulated by the same laws."

Goodsir was unquestionably wrong in certain of his speculations concerning secreting cells; as, for instance, in attributing at one time the chief part in the process of secretion to the cell wall, and at a later period ascribing the same function to the cell nucleus. He certainly had not grasped the modern idea, which, as I shall afterwards more particularly point out, considers the act of secretion as one of the results of the activity of the living protoplasm of the cell. His assumption, too, that the secreting cell invariably contains, preformed, the characteristic matters of the secretion, is one which is by no means generally true. Nevertheless, it is impossible to study Goodsir's researches on the secreting cell without ascribing to him the merit of having been the one who made the most important generalisation, connecting cell life with a definite organic function.

I may be permitted, as it were parenthetically, to refer for a moment to John Goodsir with the veneration which is natural in one who was his pupil. If it be true that the rapid march of scientific discovery has caused us well-nigh to forget the great debts which we owe to Johannes Müller, it is no less true that John Goodsir's name has passed into premature and undeserved oblivion. Goodsir's was a mind which in some respects, especially in its tastes, resembled that of Müller. He was a devoted anatomist, and studied morphology in the first instance for its own sake, but also because of the light which it sheds on organic function. He had a powerful intellect, an insatiable thirst for knowledge, a sympathy with all branches of inquiry which could throw light upon the science to which he devoted his life, and a devout and reverential spirit, which was not the less strong because it only rarely found audible, though then it was emphatic, utterance. In the earlier part of his scientific career numerous papers, for the most part short, but characterised by remarkable originality of observation and freshness of thought, seemed to promise that Goodsir would be one of the most productive of the workers of his time. A lingering illness which, without altogether disabling him, enfeebled his physical powers, and cast a gloom upon a life which had promised so much, almost put an end to his career, in so far as the scientific world at large was concerned, and henceforward he devoted his remaining energies to studies of which the results were for the most part not published, but especially to the task of teaching. Goodsir was a master who, if judged of by the low standard of fitness to instruct the great majority of his pupils in such a manner as to enable them successfully to

pass examinations, would occupy no exalted position. He possessed, however, the far rarer power of instilling into the minds of the best of his pupils that love of original inquiry, and that deep regard for truth which are the chief incentives to all scientific research of any real value.

(To be concluded.)

## ABSTRACT OF THE Bradshawe Lecture ON

### THE INFLUENCE OF THE SYMPATHETIC SYSTEM ON DISEASE.

BY E. LONG FOX, M.D. OXON., F.R.C.P. LOND.,  
CONSULTING PHYSICIAN TO THE BRISTOL ROYAL INFIRMARY.

AFTER a few preliminary observations, the lecturer announced his belief that the sympathetic system, though closely connected with the cerebro-spinal, yet possessed a certain independence of its own. This is shown not only by the observations of Parkes and Claude Bernard, by the experiments of Goltz upon vascular tone and of Vulpian upon the peripheral arterioles, but also by the fact that the fetus may arrive at full time with complete perfection of the functions of organic life, but without any trace of brain or spinal cord. Some observations were mentioned that rendered probable the existence of vaso-dilator nerves in all parts of the body.

Respecting the coarse recognisable lesions of the sympathetic, the investigations of Pió Foá, Fournier, Morselli, Colomietti, Giovanni, and others, were commented on. "The most usual lesions are pigmentation, colloid degeneration, with proliferation of endothelial cells and secondary fatty metamorphosis, interstitial hyperplasia leading to hypertrophy, and sclerosis of nerve elements; such lesions being more than enough to modify vaso-motor function, and, according to their seat, to lead to very various morbid phenomena."

Late observations on the sympathetic in phthisis were referred to, the ganglia being most diseased on the side in which the lung is most affected. But in this, as in so many other examples of coarse lesion of the sympathetic, the nerve is affected only secondarily, and must be credited, not as exciting the disease itself, but only as causing certain symptoms—flushing, sweating, palpitation, and diarrhoea, for instance. And when we see certain phenomena associated with definite lesions of the sympathetic, we are surely justified in believing that these symptoms own a sympathetic origin when the lesion of this nerve is beyond our powers of investigation. We see the starting-point of the irritation, the channels by which the irritation is conveyed, the consequence of the irritative action beyond the ganglion, but the absolute condition of the ganglion itself, in so far as it differs from its state in health, is incapable of being demonstrated, at least post mortem.

Dr. Woakes' paper at the Congress, on the Inferior Cervical Ganglion as a Correlating Nerve Centre, was referred to; and it was shown how this idea of the correlation of the ganglia could be expanded; how the influence of emotion may be seen on the cervical ganglia (blushing &c.), on the cardiac nerves, on the splanchnic, and on the abdominal plexus, especially the vesical; how, again, irritation from the various plexuses, particularly in the pelvis, travels up through the sympathetic chain and excites emotion. In this connexion, hysteria, hypochondriasis, and various other of the neurasthenias, are seen to own sometimes a central, sometimes a peripheral origin; and these diseases, when reflex, afford additional examples of the truth of Dr. Wilks's cases of sympathetic mania from tumour in the abdomen, from adherent omentum, from hernia, from misplacement of colon, and from cæcal abscess.

The influence of the sympathetic on inflammation was thus stated:—1. There is some source of irritation—cold, a blow,

a septic focus. 2. The centripetal nerves, whether sensory or not, which are within reach of this irritation, are excited more or less violently. 3. These nerves transmit to the vaso-motor centres of the region the excitation which they have undergone. 4. The tonic activity of these centres is disturbed, and suspended more or less completely. 5. So cessation or diminution of the tone of the vessels that are subordinate to these centres. 6. Consequently more or less dilatation of these vessels. 7. But this vaso-motor disturbance can only be considered as favouring the development of inflammation. It is only secondary in importance, and does not suffice of itself to make up the phenomena that we call inflammation. It places the vessels in a condition for easily and necessarily receiving more blood, it induces stasis of circulation, and offers facilities for the emigration of leucocytes; but the initial phenomena of inflammation consist in the disturbance of the intimate nutrition produced in the organised living tissue. The vitality of the cells, having been gradually lowered by the previous state of its nutrition, being thereby placed in a condition of vulnerability, is ready at any moment to respond to morbid impressions. These may be reflex, as the impress of cold, or direct, as from the presence of morbid germs in the blood; and the vaso-motor action of the vessels, which without this previous alteration of the cell nutrition would stop short at non-inflammatory congestion, is of enormous importance in determining the various stages and symptoms of the progress of inflammation, although independent and unconnected directly with the initial phenomena.

But although vaso-motor paresis has little or nothing to do directly with the initial phenomena of inflammation, there are numerous instances of indirect action. Why do we look with grave suspicion on pulmonary congestion, or a similar condition in any other portion of the system? Is it not that a region so affected is peculiarly liable to take on active mischief? A congested part becomes gradually of necessity a part in which nutrition is badly performed. The affected spot becoming less and less perfectly nourished is *ipso facto* more or less vulnerable to influences external to itself. The external influence arrives, modifies directly or reflexly still further the nutrition of a part already vulnerable, already possessing unstable cells; and the predisposition, the external influence, the modification of nutrition by the exciting cause, and the vaso-motor paresis, make up the necessary factors in the causation of inflammation.

After mentioning the mechanism of the action of the sympathetic in oedema and in various kinds of congestion, its influence on the sweat-glands, and therefore on hyperidrosis, was stated to be not a vaso-motor one, but one that depends on secreting fibres emanating from the cord through the rami communicantes to the sympathetic ganglia. Hyperidrosis is caused by a paresis of these inhibitory fibres, as is seen in certain recorded cases of coarse lesion of the sympathetic in unilateral epidrosis. A consideration of the part played by this system of nerves in general paralysis of the insane, and other diseases of the brain and cord, leads to a review of Donders' statements as to the functions of the oculo-motor, the sympathetic, and the fifth nerves in the causation of myosis, a symptom which is less frequently associated with sympathetic lesions than might be expected from the results of physiological experiment. The arguments for the vaso-motor theory of epilepsy were then stated, as well as Dr. Gowers' objections to this theory, and the lecturer remarked, "The difficulties are the greater, inasmuch as all theories must be more or less hypothetical. It seems likely that the convulsive centre in the medulla is a minute corpus striatum for collecting, modifying, radiating convulsive motor phenomena from the cerebral motor area; that epilepsy with convulsion may depend on direct or reflex irritation of this centre, but far more frequently on some condition of cells in the cerebral motor area, that may well be termed instability; that these lesions and their consequent phenomena may be wholly independent of vaso-motor disturbance; but that loss of consciousness, occurring either as an early symptom of the convulsive form of epilepsy, or as an independent phenomenon, owns as its cause anæmia of the non-motor area of the brain, an anæmia depending on vaso-motor irritation. Brown-Séquard's experiment, showing that compression of the cervical sympathetic was a valuable means against *le petit mal*, points to the truth of this latter proposition."

Some of the so-called sympathetic diseases were then passed in review—hemicrania, exophthalmic goitre, and

progressive facial hemiatrophy. The symptoms of the two chief varieties of hemicrania were mentioned, and the conclusion drawn that the symptoms of each form of this affection, especially the oculo-pupillary phenomena, point to the cervical sympathetic, or to the corresponding half of the excito-spinal regions of the cord as the part specially implicated; and the success of caffeine, quinine, guarana, and ergot in the paralytic variety, and of nitrite of amyl, carbonic acid inhalation, hot drinks, &c., in the spastic, points to the same conclusion.

As to Graves' disease, the lecturer takes the view of Eulenburg and Guttman that the exophthalmos has little, if any, connexion with the sympathetic, that the thyroid swelling is directly due to paresis of the cervical sympathetic, and the palpitation indirectly, being caused by increased action of the automatic ganglia of the heart, due to excessive blood supply from paretic conditions of the vaso-motors of the coronary arteries. He owns, however, that no explanation is very satisfactory.

The influence of the sympathetic on progressive facial hemiatrophy is far more indefinite, and can scarcely be traced, except in its connexion with the nutrition of the fifth nerve. The various forms of palpitation were then touched upon, and angina pectoris, which is very frequently a sympathetic disease, or rather a phenomenon depending on sympathetic irritation. The influence of the depressor nerve on the general circulation and its mechanism on the abdominal vessels was described. The position of the sympathetic with reference to the great question of vascular tone affects not only the vessels themselves, as in at least one form of aneurism, but more or less every morbid condition of the body. The condition of the heart reacts on arterial pressure, and arterial pressure on the condition of the heart. Modifications of vascular tone, as shown by the sphygmograph, are among the most useful elements in preventive medicine.

The vaso-motor neuroses of the extremities were next mentioned as described by Dr. Weir Mitchell, McBride, and Allan Hamilton of America, Dr. Sturge of London, Seeligmüller and Bernhardt in Germany. Most commonly the symptoms seem due to paralysis of vaso-motors entering the peripheral vessels, but there is a form that seems to own a contractile causation, and Dr. Hadden has lately suggested that myxœdema is practically the outcome of this contraction. In considering lesions of the abdominal sympathetic, and the gastric and intestinal neuralgia, the old question arises as to the length of time reflex irritation or reflex paralysis may persist; and in this relation the lecturer gave the following case: A very sensible and active shopwoman, thirty-six years of age, gave the following account of herself: She believed that she had been born blind of the right eye; at any rate she remembered when she was a very little girl being taken to see an oculist in London who said she would never see. She could not distinguish light with the right eye. In January of the pre-ent year she had a canine tooth on the right side of the mouth extracted. She immediately became conscious of light, and in a few days entirely gained sight in this eye. The optic disc and retina were perfectly normal, yet for thirty-six years she was quite blind, apparently from some reflex influence connected with the alveolus of the canine tooth.

In considering diabetes mellitus, it may be said briefly that the influence of the sympathetic system is very great in this disease. It includes direct or reflex lesions of a bulbar centre, or lesions so near as to be almost direct, hyperæmia of liver, sometimes stasis in the capillaries of the general circulation, an influence on the secretion of glycogen, and of the ferment necessary to its transformation. Paresis of the renal vaso-motors, sometimes dependent on lesion of a minute spot on the floor of the fourth ventricle, induces diabetes insipidus, and this is still further proved by the fact that this morbid condition can be cured by faradisation over the kidney, and by the administration of ergot.

The whole subject of pigmentation is peculiarly in the domain of the sympathetic. Jaschowitz divided the sympathetic in the spleen, and caused increased flow of blood and a copious deposit of hæmaturic pigment in its cells. There is a marked connexion between pigmentation and anæmia under certain conditions, as the former is frequently associated with a splenic cachexia, in which there is a destruction of red globules. The morbid state of blood, whether caused by direct lesion of abdominal organs or plexuses, by influences acting from without or mental shock, will induce some stasis of blood current, an important factor in all pigmentation. We have first lesion of sym-

pathetic ganglia, especially in the abdomen, influencing the production of pigment, then the circulation of abnormal blood in the vessels, reflexly influencing their calibre, then stasis of greater or less intensity, then pigmental deposit. This has been seen in Hodgkin's disease, in pernicious and other forms of anæmia, in cerebro-spinal sclerosis. Dr. Guéneau de Mussy speaks of staining in the face in phthisis as a sign of the presence of abdominal tubercle; whilst irritation of the solar plexus by experiment, or by the presence of cancer, has been proved to cause the appearance of numerous pigment granules in the blood, and to cause their deposit in the skin. Again, irritation originating in the uterine region, especially during pregnancy, causes pigmentation almost universally. Dr. Swayne's case of a lady in whom black pigmentation of the arms and hands occurred in each pregnancy has been already recorded in the Transactions of the Obstetrical Society.

In Addison's disease the changes have been well defined as: (1) A lesion of the sympathetic nervous system. (2) Inflammatory processes in the connective tissue of the suprarenal glands. (3) From the products of the inflammation ensues a paralytic condition of the vaso-motor fibres of the sympathetic, and consequently an imperfect distribution of blood. (4) On this is to be saddled all the phenomena of the disease: anæmia, disturbance of nutritive functions, bronzed skin, and a secondary affection of the blood.

*En résumé*, we may say that in congestion, in hyperidrosis, in some forms of angina pectoris, in sunstroke, in the regulation of vascular tone and in its many abnormalities, in vaso-motor neuroses of the extremities, in symmetrical vaso-motor gangrene, in some varieties of aneurism and of albuminuria, of diabetes mellitus, in diabetes insipidus, in hysteria, hypochondriasis, and other forms of neurasthenia, in those protean disturbances of the economy that are excited by emotion; and lastly, in pigmentation, including Addison's disease—the influence of the sympathetic seems primary and almost, if not wholly, independent. In inflammation, including practically inflammatory diseases of all organs, in fever, in hemicrania, exophthalmos, progressive facial hemiatrophy, and in epilepsy, the part played by this system of nerves is secondary, though important. In most of these, however, as of other ailments, the cardiac phenomena, the conditions of vascular tone, the perspiration and diarrhoea, the marvellous influence of the abdominal nerves and vessels on the distribution of blood in the body, are evidences of collateral and coincident disturbances of the sympathetic.

## THE SELF-LIMITED DURATION OF PULMONARY PHTHISIS.<sup>1</sup>

By AUSTIN FLINT, M.D., LL.D.,  
PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE AND  
CLINICAL MEDICINE, BELLEVUE HOSPITAL, NEW YORK.

THE title of the paper which, in compliance with a courteous invitation, I have the honour to submit to the section on Medicine may require some explanation. By the name pulmonary phthisis I mean the chronic affection so-called and studied half a century ago by Laennec, Louis, Connell, and their contemporaries. The history of this affection as contained in the medical literature of the last quarter of a century, illustrates the mutability of pathological doctrines, and the evils liable to ensue when the connexion which should exist between histological and clinical studies is severed. This is not the time nor place to consider the instructive lessons to be learned from this history. Suffice it to say that, at last, the teachings of histology coincide with those of clinical experience, and that now, after the lapse of fifty years, the names chronic phthisis and tuberculosis are again synonymous. By the term "self-limited" I mean the duration of a disease as determined by its intrinsic tendency—that is, irrespective of either medicinal or any extrinsic agencies. The term was introduced by the late Professor Jacob Bigelow in a discourse published in 1835. Quoting his definition, he says: "By a self-limited

disease I would be understood to express one which receives limits from its own nature, and not from foreign influences." He cited whooping-cough, measles, scarlet fever, small-pox, erysipelas, and typhoid fever as diseases which run a certain course and end after a certain time from their intrinsic limitations. This doctrine has lost the novelty which it had at the time of the publication of Bigelow's discourse. No one at the present day will dispute the doctrine as applied to certain diseases. Within late years the list of self-limited diseases has been extended. To the essential fevers (the eruptive, the continued, and the periodical) have been added acute pneumonia, acute articular rheumatism, and acute dysentery.

My object in this paper is to show that pulmonary phthisis may have a self-limited duration; that, in a certain proportion of cases, this disease ends favourably, irrespective of any appreciable extrinsic agencies, recovery taking place, provided the nature and extent of the local lesions be not such as to render them either irreparable or innocuous. If the doctrine of self-limitation as applied to phthisis be not entirely new, it has, at all events, received as yet very little consideration in medical literature and in medical practice. If the doctrine in this application be true, it has important pathological and practical bearings, to some of which I shall briefly advert.

How is self-limitation to be proved as applied to phthisis or to any other disease? Facts pertaining to morbid anatomy and to therapeutics may render the application of the doctrine probable; but, evidently, positive and complete proof can only be afforded by a collection of cases in which the disease pursued its course without active interference in the way of treatment, either medicinal or hygienic, and without notable changes in habits of life, or in any of the conditions under which the patients were situated when the disease became developed. For obvious reasons these requirements for absolute proof are not easily obtained in cases of a disease like pulmonary phthisis. Yet cases involving these requirements occasionally come under medical observation. The hopeful mental state which generally accompanies phthisis sometimes leads patients to trust altogether to nature for restoration to health, and to continue their usual manner of living without any alteration. Some patients do this from a conviction that they have not a malady of sufficient consequence to claim attention, beyond, perhaps, palliative remedies; and some from circumstances which render it difficult to do otherwise. Again, there are phthisical patients who do nothing in the way of either therapeutics or hygiene from a thorough scepticism as to the advantage of doing anything. Hence it is practicable to collect from a field of observation sufficiently large, during a term of years, a certain number of cases which exemplify the natural history of phthisis.

In 1858 I had collected a considerable number of histories of cases of phthisis, recorded during the preceding twenty years of medical practice, and I was led to examine the collection for those cases in which there had been an arrest of the disease. Twenty-four cases were in this category. The histories of these twenty-four cases were analysed with reference to points of agreement in the management; I assumed that in the points of agreement must lie the means by which the disease had been arrested, provided these points of agreement were not equally common in other cases in which the disease was not arrested. A striking result of this analytical study was, that in a few cases no appreciable influences, either of medication, diet, or regimen, had been brought to bear on the disease; the patients took no active remedies, and continued unchanged the same habits of living as before the development of the disease. It seemed a logical inference that in these cases the disease was not arrested, but that the recovery was owing to an intrinsic tendency thereto; in other words, the disease ended in recovery from self-limitation. An abridged account of the histories of these twenty-four cases was embraced in a report published in the *American Journal of Medical Sciences*, January, 1858.

In 1863 I had accumulated additional cases, in which the disease had either been arrested or ended from self-limitation. The number amounted to sixty-two. These cases were studied analytically in the same way as those analysed in 1858. In seven cases no medicinal or hygienic measures of management were employed. The recovery in four of these cases was complete. In three cases good general health had been regained and maintained for a long period, some cough and expectoration remaining. An abstract of the histories of the sixty-two cases was published in

<sup>1</sup> Read at the British Medical Association, Worcester, August, 188

the Transactions of the New York Academy of Medicine for the year 1863.

In 1875 were published, in a work entitled "Phthisis in a Series of Clinical Studies," the results of an analysis of the histories of all the cases of phthisis which I had recorded during a period of thirty-four years, the number being 670. Of these 670 cases forty-four ended in recovery. Details of the history of each of the forty-four cases are given in the work sufficiently to render evident the recovery and the correctness of the diagnosis. In addition to these forty-four cases there were thirty-one cases in which the disease ceased to progress, and remained non-progressive for at least several months, and in most instances for several years. In these thirty-one cases the phthisical disease was considered as having ended, complete recovery not taking place in consequence of irreparable lesions. As cases for analytical study with reference to the agencies which may have caused the arrest of the disease, these thirty-one cases of non-progressive phthisis seemed hardly less valuable than the forty-four cases which ended in complete recovery. Adding together the two groups of cases, out of the collection of 670 recorded histories of phthisis, there were seventy-five in which the disease either ended in complete recovery or remained for a long period non-progressive.

These seventy-five cases offered a rich field for analytical study with reference to several points of inquiry having important bearings on prognosis and treatment. The only point to be here noticed is the proof which some of the histories furnished of the recovery or the non-progression being due to an intrinsic tendency of the disease. In how many of these cases was it evident from the histories that the disease was not arrested by either medicinal or hygienic treatment? The answer to this question furnishes the proof of self-limitation.

Of the forty-four cases ending in recovery, in twenty-three there was no medicinal treatment to which arrest of the disease could be attributed. In several of the twenty-three cases there was no medicinal treatment; in the remainder of the cases, the treatment consisted of simple tonics, palliatives of cough, or remedies to meet some other symptomatic indications. In none of the cases could the medicinal treatment be considered as curative. Of the thirty-one cases of non-progression of the phthisical disease without complete recovery, in fifteen there was no medication by which it might be supposed the disease had been controlled, and in several no medicinal treatment whatever. The two groups of cases—namely, those ending in recovery, and those becoming non-progressive without recovery—thus furnished about an equal proportion of those in which medicinal treatment was either wanting, or in no degree curative, the proportion in the first group being twenty-three of forty-four, and in the second group fifteen of thirty-one. This correspondence in the two groups has perhaps a significance beyond mere coincidence. In respect of hygienic or non-medicinal treatment, in some cases of both groups there was no change whatever in habits of life or other circumstances. In other cases there were changes involving improved hygienic conditions, but in a considerable number the changes were of a character that a potential influence could not be attributed to them. It is probably correct to say that the changes may have favoured the recovery or the non-progression, but that they were inadequate to arrest the disease. In my work is introduced a condensed history of each of the seventy-five cases, which form the two groups now referred to.

A self-limited duration cannot be inferred from a single case, or from a very few cases, for this reason: the course and termination may have been affected by influences which are extrinsic, but not apparent. In order to obviate liability to error on this score, the number of cases must be sufficient to render it impossible, or vastly improbable, that in all such influences could have been overlooked. It is needless to say that the cases from which the inference of self-limitation is drawn must have been carefully observed and honestly recorded. Another requirement is essential—namely, there must be no room for distrusting the accuracy of the diagnosis. Assuming competency for observation and veracity, the diagnosis in each of the seventy-five cases is attested by the recorded histories, and it will be admitted that the number of cases is sufficiently large for the exclusion of error on the score of unrecognized extrinsic influences. The number of cases might be increased by the addition of those which have come under observation since 1875. This seems to me needless with a view to strengthen the conclusion

respecting self-limitation. I therefore submit, as substantiated by the clinical facts which I have cited, the following proposition:—Pulmonary phthisis, in a certain proportion of cases, has a self-limited duration, the disease ceasing to exist after more or less progress of the local affection, all symptoms referable to the lungs disappearing, and recovery, as regards the general health, being complete. The disease is also self-limited in a certain proportion of cases in which lesions remain, giving rise to more or less of cough and expectoration, the persistence of these lesions not being incompatible with good general health and long duration of life.

Many topics of interest and importance cluster around this proposition. It is an interesting fact that self-limitation is exemplified in the majority of the fatal cases of phthisis. As is well known, the disease, as a rule, advances not by a continuous progress, but by a series of successive invasions separated by variable intervals. After each invasion, or as it has been termed, tuberculous eruption, there is temporary self-limitation of the disease. I will not venture on a discussion of the question whether this fact is sufficiently explained by the statement that each eruption of tubercles for a time exhausts the tuberculous cachexia, or whether the fact be owing to the production of successive broods of the bacilli tuberculae. It suffices to state the clinical fact. The fact suggests a capital object in the treatment—namely, prevention of a renewed invasion. The continuous advancement of the disease, as an exception to the rule, is the pathological feature of the so-called "galloping consumption," or phthisis florida.

In the cases ending favourably, which have been referred to as furnishing proof of a self-limited duration, the diagnostic symptoms and physical signs were so well marked as to leave no room for doubt as to the existence of phthisis. From cases which have come under my observation, I have been led to believe that not very infrequently phthisis ends by self-limitation without having advanced far enough for the diagnosis to be considered as positive. A patient has had for some time a slight cough, either dry or with a scanty expectoration; there has been some loss in weight, and the body heat is somewhat raised, with, perhaps, spitting of blood. These symptoms, taken in connexion with the age of the patient, and, it may be, grounds for suspecting a congenital predisposition, point to a tuberculous affection. But examinations of the chest in such a case may fail to reveal distinct physical signs. Very likely the problem, as regards the physical diagnosis, is to determine whether at the summit of the chest on the right side there are abnormal signs or only the normal points of disparity between the two sides. There may be found only a subcrepitant r le, or slight pleuritic rubbing, or an interrupted respiratory murmur at the summit on one side, without conclusive evidence of tuberculous solidification. Under these circumstances, the physician either commits his judgment to a diagnosis of incipient phthisis, or, as is more probable, he reserves an opinion for further developments. After a short time all the pulmonary and general symptoms disappear. Now, if incipient phthisis have been dignified, the physician concludes that the diagnosis was erroneous. He feels obliged so to conclude in consequence of the common belief that phthisis does not thus commence and end from self-limitation. But it is highly probable that the diagnosis was correct. Phthisis existed and ended in its incipency. It would be proper enough to distinguish these as cases of abortive phthisis. If I mistake not, all medical observers of much experience will admit that the foregoing sketch represents a class of cases not extremely rare. That they are not very rare is a fair inference from the frequency with which the traces of an old, small phthisical affection are found in bodies dead with other diseases than phthisis.

A topic of practical importance is the bearing of self-limitation on the prognosis in individual cases of phthisis. The analytical study of my collection of cases showed that, as a rule, in those which ended favourably from an intrinsic tendency, the tuberculous affection was moderate or small in amount, but that there are exceptions to this rule. All observers of much experience will agree that the prognosis in cases of phthisis is to be based more on the general condition of the patient than on the local symptoms and signs. To consider the elements of prognosis would be here out of place, even if time permitted. In general terms, the symptoms which denote tolerance of the phthisical affection are those which indicate a favourable intrinsic tendency, and, on the other hand, pyrexia, progressive loss of weight,

frequency of the heart's action, and anorexia, point to an opposite tendency. Of special importance, in a practical view, is the bearing of the doctrine of self-limitation on the conclusions to be drawn from observations respecting the agency of therapeutic and hygienic measures in the treatment of cases of phthisis. How many and various are the remedies which have been supposed to have been sometimes curative in cases of this disease! Instances of their apparent curative power have been attested by honest observers. Making the fullest allowance for errors in diagnosis, I cannot doubt the credibility of more or less of these cases. Recovery has taken place under the employment of divers remedies; yet these remedies have so generally failed that, for the most part, they are now obsolete. The explanation of their apparent efficacy is to be found in the doctrine of self-limitation. The disease ended favourably, not from a specific influence of the remedies, but from an intrinsic tendency. This is not saying that the remedies may not have been, to a greater or less extent, serviceable. It may be laid down as a principle applicable to all diseases that whenever experience has seemed to show success from treatment by a variety of remedies the efficient cause lies in the disease itself. This principle becomes more evident the more we become acquainted with the natural history of diseases. To accept this principle is not to disparage medicinal treatment. In certain cases of phthisis, as of other diseases, self-limitation is a factor co-working with curative measures, and, as perhaps may be added, sometimes effective, in spite of measures which obstruct its operation. On the other hand, when this factor is feeble or wanting, curative treatment is not likely to prove of much avail. Evidently, in drawing conclusions respecting the curative effect of remedies allowance is to be made for this factor. The extent of its co-operation, doubtless, differs much in different cases, in some being sufficient in itself, and in others either considerable, or moderate, or slight.

The doctrine of self-limitation bears on the climatic and other measures entering into the hygienic treatment of cases of phthisis with not less force than on the employment of drugs. As regards climate, is there a practical theorem more perplexing to the practitioner of medicine than that of selecting the best resorts for phthisical patients, provided the selection be made on the basis of an impartial consideration of the reported results of climatic agencies in different situations? Underlying the exaggerations on the one hand, and on the other hand the depreciations of particular climatic resorts, founded on the different results in a few cases, is the factor of unknown power, self-limitation, the existence of which is generally ignored. Here is the explanation, at least in part, of the discrepancies of testimony concerning the results of climatic influences in different situations.

I forego reference to topics relating to the subject of this paper other than those briefly adverted to, feeling that I may have already overstepped the privilege of an invited guest. In conclusion, it must be admitted that the characteristics of the medical practice of to-day have resulted, in no small measure, from the knowledge which has been acquired of the natural history of diseases. And the practical applications of this knowledge have had relation especially to the doctrine of self-limitation. Bigelow, when he distinguished certain diseases as self-limited, probably had but a faint apprehension of the scope of this well-chosen term. The boundaries of its fullest extension have yet to be ascertained. Much knowledge of the natural history of diseases still remains to be acquired. It could hardly have been conjectured by Bigelow, when his discourse was written, that phthisis would be included among the self-limited diseases. The extent of influence attributable to self-limitation in this disease is by no means as yet ascertained. There is ample room for observations bearing on this point of inquiry. Impressed with the importance of clinical studies having this direction, I cannot forbear the remark that they promise more in the way of practical utility than has hitherto been derived from the discussion of the histological and pathological questions which, of late years, have engrossed so much attention and occupied so large a space in medical literature.

THE funds of several institutions in Lancashire have largely benefited by the will of Mr. Asa Lees, who died recently. The Oldham Infirmary receives £10,000; Owens College £10,000; the Royal Albert Asylum for Idiots £10,000; the Northern Counties Supplementary Hospital for Chronic and Incurable Diseases £2000.

## A METHOD OF APPLYING LIGATURES TO VEINS.

By HENRY SYDNEY, M.D., C.M.

IN applying a ligature to a vein, or adopting any mode of occlusion, inflammatory action is both inevitable and requisite. The form of phlebitis required is the healthy aseptic variety, with its limiting zone of plastic formation passing across the lumen of the vein and its solidified contents and preventing purulent matter or the results of disintegration from entering the circulation. The variety to be dreaded is the septic, where phlogogenous matter, zymotic or chemical, penetrates the tissues before the defences of the limiting zone can be formed, and diffuse suppuration is the result. If septic inflammation were due only to germs introduced from without, it might be hoped that strict antiseptic precautions would prevent it, but there is every reason to suppose that it can arise from the formation and absorption of a material not of a zymotic but a chemical nature, due to decomposition or retrograde metamorphosis of tissue or wound products. According to Billroth, the surface of a healthy granulating sore or a zone of healthy plastic formation is impermeable to septic organisms, but where, from the presence of crushed or devitalised tissues, the wound is unhealthy, septic material, either formed within or introduced from without, can be absorbed into the system. Now, in the ordinary mode of occluding veins by acupressure or subcutaneous ligature there is, in addition to the vein, a large amount of skin and other tissues seized, compressed and more or less devitalised; and consequently conditions are produced favourable to unhealthy tissue metamorphosis and absorption. This may appear a theoretical rather than a practical view, or a refinement of the septiphobia, now so extensively prevailing in the surgical portion of the profession, but it is nevertheless a very palpable possibility, if not probability, and one which, in view of the still questionable reputation of operations of complaisance on veins, cannot be allowed to pass unheeded. But from whatever point it is viewed, the principle of enclosing within ligature or acupressure tissues other than the vessel to be occluded is wrong, and whatever proceeding tends to limit the action of the ligature to the vessel only, excludes an element of danger. Whether the dangers of operation on veins are exaggerated or not, it is easily conceivable how on these busy highways of the system results are apt to follow grave in proportion to the ease with which, ceasing to be local, they become general, and therefore an essential precaution in operations is antiseptic procedure. A punctilious regard to cleanliness may obviate the employment of the redundant ceremonial of full antiseptic measures. Either the spray or the irrigator may be used. I have, when operating by ligature, had equally good results from both. I have also had perfect freedom from suppuration and sepsis, without either spray or irrigator, from an application to the skin of a thick ointment composed of wax, olive and eucalyptus oil and carbolic acid. This smeared over the parts forms a coating sufficiently thick, at the temperature of the skin, to prevent the contact of air with the punctures. In regard to the operation itself, it should, after the plan of Ricord and Duncan,<sup>1</sup> be subcutaneous, and the ligature of catgut. The ligature should be very fine: No. 1 size only. This for two reasons: because it requires less force to cause complete occlusion of a vessel with a thin than with a thick ligature; and a thick ligature embraces a greater portion of tissue, and therefore causes a greater amount of bruising and destruction. The disadvantages and even the danger, in the case of arteries, of using thick catgut, have been pointed out by Mr. Barwell<sup>2</sup> and Mr. French.<sup>3</sup> The ligature should not be in that rigid condition in which it usually is from being kept in carbolic oil, as, after soaking in the fluids of the wound, it becomes softened and elastic and in that condition stretches after tying, which, be it ever so little, is sometimes sufficient to prevent perfect occlusion. To soften the ligatures, they may be soaked in a 5 per cent. solution of carbolic acid before being used. I find that the addition of a small quantity of eucalyptus to the carbolic oil in

<sup>1</sup> Duncan, British Medical Journal, July, 1881.

<sup>2</sup> THE LANCET, July 30th, 1881.

<sup>3</sup> Ibid., Nov. 19th, 1881.

which they are usually kept makes them soft and elastic. In this condition, as in tying with horsehair, a double turn must often be made in the first knot, to prevent it slackening before the second can be brought to fix it. The vein only, with as little surrounding tissue as possible, should be included in the ligature. Not only is there less tissue bruised or devitalised, but less force is required to produce complete occlusion, just as an artery is more easily controlled by pressure on its bared trunk than over superimposed structures. With this object I employ two needles—a long sharp-pointed one, and a blunt grooved one to act as a director. The sharp needle is first thrust underneath the vein, and its point brought out through the skin on the opposite side. It is then withdrawn a sufficient distance in its track to allow of its point being passed over the vein between it and the skin. To serve as a guide, the grooved director is now inserted in the puncture of exit from which the needle has just been withdrawn, and the needle, now pushed on, meets the groove of the director and comes out at its former aperture. The subjoined diagram (Fig. 1) shows the lines of puncture, which include the vein, with some surrounding tissue. After these tracks were made, I

FIG. 1.

A E C F B, Track of first puncture under the vein, v. E, Point to which the needle is withdrawn. E D F, Track of puncture over the vein. F, Point at which the groove of the director at B meets the needle to conduct it out at its former channel, F B.

formerly used blunt needles and a director to pass the ligature round the vein and tie it. Latterly I have used a triangular-pointed needle five inches in length, with an eye in the middle and a bulbous extremity. It is thinner in the shaft than at the point, so that the ligature threaded through its centre passes without hindrance along with it into the puncture. The needle, with about eight inches of ligature, is thrust under the skin beneath the vein and brought out on the other side, as just explained. It is pushed on till the ligature appears, one end of which is then withdrawn sufficiently to allow it to be passed over the vein, guided out by the director as described, and pushed on till the other end of the ligature can be pulled through. At this stage of the operation, the position of the vein, the ligature, and the needle is as shown in the annexed diagram (Fig. 2).

FIG. 2.

a, Ligature drawn through after first transfixion under the vein, v. a, Ligature carried over the vein and coming out at the same orifice as b.

The ligature now forming a loop around the vein is drawn out of the needle, tied in a single knot, and that end of it which was first passed through is drawn back by the needle to the other side of the vein, and the knot passing under the skin, is then tightened. To tie again and complete the reef knot, the eye of the needle bearing the ligature must again be pushed through, and the knot tied as in the first instance; the other ligature is brought back in the needle, which may now be entirely withdrawn, and the knot made fast. The ends are now cut off as near to the knot as possible; this is done by pulling gently on the one-half of the ligature, and cutting it off close to the skin, so that it at once disappears beneath it when divided; the other end is similarly dealt with. The vein is now tied with a reef knot, which with both of its ends is beneath the skin. In this proceeding it will be observed that till the completion of the operation the needle is never withdrawn entirely out of the wound; and that it is by means of the eye carrying the ligature from one side to the other that the knot can be correctly and securely tied subcutaneously. To ensure more complete and permanent adhesion, as well as to avert clotting in the vein, two ligatures must be applied, at intervals not

exceeding an inch. The lower ligature to be first applied, and before tying the knot of the upper one all the blood in that part of the vein between the two points of occlusion must be pressed out, so that the sides of the vessel are brought into the closest contact. By this means a much firmer adhesion is obtained than through clotting and subsequent contraction and occlusion. Broca<sup>4</sup> lays great stress upon the different results of stability of obliteration of veins, produced by coagula and by adhesion of walls. The latter mode of adhesion he asserts to be more solid even than that which takes place between the pleuræ; whereas the other is frequently but temporary. The formation of thrombus is to be prevented, in the first place, as urgently pointed out by Erichsen, by keeping the ligature out of the vein; when from the pressure of hæmorrhage, of which there should not be any, there is reason to suppose the vessel is pierced, operation on that spot must be at once stopped, and another chosen. In the second place, by firm pressure on the limb, previous to any ligaturing, by means of a rubber bandage applied from the foot up to that part immediately below the spot chosen for operation. By doing this the veins are emptied of their contents, so that no thrombus with secondary phlebitis can result. For the same reason the bandage is also to be continued over and above the ligatured portions as the operation proceeds. The application to each of the punctures of a small piece of lint moistened with carbolic oil and covered by absorbent carbolized wool completes the procedure. Unless there is much pain, the dressing need not be removed for three or four days. During this time the patient is to be kept in bed; on the fifth or sixth day, according to the amount of tenderness, the leg may be put to the ground. It is seldom that I have seen suppuration except when thick ligatures have been used or when a large portion of tissue has been included. It has never, in any case, amounted to more than two or three drops of pus, which, after making its way out of the punctures, was immediately followed by healing. As I remarked, the application of two ligatures, less than an inch apart, is the surest means to produce obliteration; in ordinary cases two, or at most three, such obliterations are sufficient to relieve ordinary varicosity. In eighteen cases of operation where the measures and precautions I have enumerated have been observed, I have seen no bad results, or, indeed, any that caused the slightest anxiety. In one instance, that of a person about fifty-five years of age, in whom the saphena was tied six inches above the knee, an acute attack of gout developed, affecting the great toe of the limb operated upon. So far as I am able to judge during two years I have adopted these methods, the results have been permanent upon the vessels ligatured. The most satisfactory cases of all, probably because the disease in the veins was in an early stage of development, were those of some young military cadets upon whom I operated. The varicosities before operation were such as would have disqualified these gentlemen for the service.

In long-standing cases where there is much œdema and great tortuosity of vessels, there are considerable difficulties to encounter. In regard to these, Mr. Duncan's paper, already referred to, gives some valuable suggestions; amongst others, to facilitate the application of the ligature, he advises that a tight rubber band be placed high up round the limb; this, while it brings the veins out in strong relief, has the additional advantage of rapidly and surely showing by hæmorrhage whenever they are wounded. He has also found that a rubber bandage well applied and kept on for some time reduces that solid brawny œdema so frequently met with in varicose disease, in which the vessels run like gutters beneath the skin and render deligation difficult.

In conclusion, I need hardly observe that the method and precautionary procedures here set forth lay no claim to originality. The method, indeed, is synthetical, composed of elements selected from such procedures of others as promise the greatest immunity from the peculiar dangers which are understood to attend operations on venous tissues. Its details may appear complicated and superfluous; but with the facts of the later investigations of surgical pathologists before us, and the knowledge of how completely in the instance under consideration the results are dependent upon healthy inflammatory action, distinguished from that due to septic causes, there is an enhanced disposition to sacrifice expedition in method to correctness in principle, and to stoop to what may appear tedious minutiae to ensure safety.

Hounslow.

## OPERATION STATISTICS OF THE GLASGOW ROYAL INFIRMARY.

BY M. THOMAS, M.D., F.F.P.S. GLAS.,  
SUPERINTENDENT TO THE INFIRMARY.

As the statistics of operations given by Sir James Simpson are oftener quoted than those of any other authority, it occurred to me, after finishing the paper which appeared in THE LANCET of July 1st, to make an exact comparison, and on the same lines, of the operations performed here from 1868 to the present time. This is a continuation of

the statistics of this hospital, as given by Sir James, of the previous eighteen years. The subjoined table shows the very satisfactory results.

The decrease in the fatality of the operations during the last thirteen years ranges from 16·8 to 4·6 per cent. There is an increase of 13 per cent. in only one set of amputations—viz., secondary for disease of the forearm.

The total number of cases for the thirteen years was 822; deaths, 212; or 25·5 in every 100, against 39·1 as given by Sir James.

The total number of amputations for injury was 397; deaths, 126; or 31·7 per cent., against 43·6 per cent.

The total number of amputations for disease was 425; deaths, 86; or 20·2 per cent., against 33·8 per cent.

### RESULTS OF THE FOUR AMPUTATIONS OF THE THIGH, LEG, AND FOREARM, IN THE GLASGOW ROYAL INFIRMARY, IN THE SAME MANNER AS GIVEN BY SIR JAMES SIMPSON IN HIS PAPER ON HOSPITALISM.

	PRIMARY.								SECONDARY, FOR DISEASE.							
	Thigh.		Leg.		Arm.		Forearm.		Thigh.		Leg.		Arm.		Forearm.

	44·0		39·8		20·8		9·0		21·9		17·6		17·5		18·4*	
	60·0		53·7		37·6		13·6		38·4		32·9		26·0		5·2†	

\* Mortality per cent.

† Mortality per cent. of the previous eighteen years, as given by Sir James Simpson in his paper on Hospitalism.

#### Mortality of the Four Major Amputations, combining together Operations for Injuries and Operations for Disease.

Per cent.			
Thigh	cases, 380; deaths, 113; mort., 29·7, agst. 46·2		
Leg	„ 182; „ 54; „ 29·6, „ 44·0		
Arm	„ 167; „ 33; „ 19·7, „ 35·4		
Forearm	„ 93; „ 12; „ 12·9, „ 11·7		

In addition to the decreased mortality, which I attribute chiefly to the use of antiseptics, another noticeable feature in these statistics is the increase in the number of operations. In eighteen years the number was 661; for

the last thirteen years the number was 822; an increase of 19 per cent. It is to be hoped the mortality will continue to decrease, but I fear it will never reach the low percentage of country operations, as cases of the worst description are occasionally sent to us from some of the very districts mentioned by Sir James as places where success had been achieved, such as Motherwell, Airdrie, &c. It is impossible that cases coming so far can have the same chance as those treated at home; but there can be no doubt it is the discomfort of their homes which forces the country practitioner to send them into the infirmary. Small hospitals in such localities would be an immense boon to the poor sufferers, and their erection is only a question of time.

## MODERN STUDY OF MICRO-ORGANISMS, AND ITS INFLUENCE ON MEDICAL THOUGHT.<sup>1</sup>

BY SOLOMON CHARLES SMITH, M.D.,  
SURGEON TO THE HALIFAX INFIRMARY.

I WISH to draw attention to the position to which recent researches on bacteria have brought us in regard to the interesting question of the relation between micro-organisms and disease, partly because the subject is a most thought-producing one, partly because it is one in the investigation of which great strides have lately been made, and especially since in its elucidation we have now arrived at a point from

which research may advance along two separate lines, each useful when checked by the other, but liable to lead to error if prosecuted alone, and because there is great temptation to us all, in consequence of the brilliancy of the results lately obtained, to rush into the microscopic line of inquiry as to the nature of the germs of disease, to the exclusion of that other line of research, which I think is so important, as to the nature of those conditions which make man's body a fit nidus for the hatching of those germs, and the development of the diseases to which they are related. All our knowledge on this subject is new: the discovery of the yeast plant only took place in 1835, the trichophyton of ringworm ten years later, and the relation between living germs and suppuration only fifteen years ago; but the demonstration of the spirillum of relapsing fever, the bacilli of anthrax, of enteric fever, and now of tubercle, are things of the very present. And it seems probable that the widening of the circle of diseases which must be considered infective resulting from this new knowledge will lead to some modification of

<sup>1</sup> Read before the Yorkshire Branch of the British Medical Association held at Leeds, July 26th, 1882.

our ideas as to the nature of the infective process, and make us look not so exclusively to the germ as the all-powerful principle, but take greater cognisance of the preparedness of the individual to become a fit breeding ground for its growth and development. Even in what may be called laboratory experiments, attention to these two factors is found necessary in the cultivation of certain bacteria outside the body. The nature, the composition, and the moisture of the material upon which they are grown, and the temperature at which the experiment is conducted, are points upon which success or failure hinges—that is, these organisms develop readily enough if the conditions are suitable, but not otherwise. This did not escape the observation of Professor Tyndall, for in his researches he found that although the ordinary bacteria of decomposition were able to grow in every organic solution, still there was a considerable difference in the readiness with which they developed in the various kinds of infusion experimented on, the tubes containing some being far gone before those containing others were sensibly affected. "Two bacteria germs of equal vital vigour dropping from the atmosphere, the one into a neutral or slightly alkaline, the other into an acid, infusion, soon cease to be equal in vigour; the life of the one is promoted, the life of the other only tolerated, by its environment." "A germ brought close to the death point in a neutral or in an alkaline infusion may revive, while in an acid one it may perish; just as proper nutriment may rescue a dying man, while improper nutriment would fail to do so."<sup>2</sup>

Now, just as in these experiments fitness of soil was essential for growth of bacteria, I think we must look upon that rapid growth of micro-organisms which occurs in infectious disease as due not merely to an infection with certain germs, but to the existence of such a state of body as shall supply fit and proper food for their development. The list of diseases in which micro-organisms have been found is a long one, but till quite recently, although their constant association with these ailments was undoubted, the proof was wanting that they were actually their cause; but now we are told that in phthisis, which has long been known to be infective within the individual, and suspected to be contagious from one person to another, the contagium does actually reside in the bacterium, which has lately been discovered in that disease.

In the older methods of investigation by inoculation with morbid fluids, it was always difficult to prove that the bacteria which they undoubtedly contained were themselves the real producers of disease, and that the virulence did not lie in the fluids themselves; but Dr. Koch's researches carry us a long way out of this stage of doubt. In his investigations into the origin of tubercle he has not only demonstrated the existence of bacteria of special form, but has been able to cultivate them outside the body. This he did on soft gelatinous plates, upon which he found they would grow, which he inoculated successively one from another, so as to eliminate all chance of carrying forward any of the original morbid material; he then introduced these bacteria of the tenth generation into healthy animals with this result, that in their development and multiplication they again produced in these animals the same tubercular disease as their predecessors had caused in those from which they had originally been taken.

The interest of this discovery is enormous, since it not only puts phthisis among infectious diseases, but it proves that the living bacteria are themselves the actual infective particles. Everyone who has watched medical and even non-professional literature during the last few months, must have been struck with the great influence this has had upon medical thought, leading physicians to increased advocacy of isolation, separation, and antiseptics, and urging pathologists on, even in the face of the Vivisection Acts, to still greater efforts to trace out the life-history of a multitude of new micro-organisms. The journals are filled with descriptions of antiseptics, inhalations, and respirators, and other means of bringing parasiticide remedies into action against diseases which have not hitherto been looked upon as parasitic, and it would be difficult to say how many earnest microscopists are not now at work cultivating and classifying micro-organisms, with such effect that already the list of bacteria, bacilli, and micrococci found in different diseases is both long and intricate. Now, in all this good work knowledge is gained, but what I wish to point out is that these microscopic researches on bacteria will be practically useless

unless embodied with investigation into the causes which make the living body a fit breeding ground for them; and as these two lines of inquiry are fairly distinct, are likely to be undertaken by different men, and are in harmony with different modes of thought, I urge that we ought not to wait for more knowledge of bacteria, nor ought we all to enter the same field of minute microscopic research which has lately been so fruitful, nor especially ought we, because we do not all possess high objectives, to stand aside and consider ourselves out of the running, but should all do what we can to discover this other factor in the production of disease, convinced that there is full scope for ordinary clinical observation in the search for those conditions of health and surroundings which make man fit food for bacteria, fit soil for the growth of those micro-organisms which in their different modes of development produce the various forms of infectious disease. The researches on bacteria which have recently been made tell us plainly that they produce diseases which carry men off, but they do not give the reason why one is taken and the other left, and till we discover this other factor the germ theory does not cover the whole ground, does not explain all the phenomena. So long as germs were thought only to be concerned with what were then looked upon as infectious diseases, it was always possible to imagine that such individuals as had escaped illness had really escaped germs, but now that bacteria are held to be causative of other diseases which we always have in our midst, and which we obviously escape much more often than we catch, it becomes necessary to add to the bare and naked germ theory the hypothesis that there is a varying resisting power in living tissue, and that germs do not always find it a fit nidus for their development and multiplication. This is a necessary addendum to the germ theory, for without it too much is proved, and we ought all to be long since dead. What, then, are the conditions of health and of surroundings which so degrade the vitality of man's tissues as to render them a fit breeding ground for bacteria? This is a question as difficult as it is important, and one the answer to which is only to be found by patient observation of cases in the new light thrown upon them by the theory of specific germs. It is worth while bearing in mind, however, that there is a great variation in the comparative importance of the two elements in the etiology of different diseases, in some the contagium, in others the fitness of soil or the receptivity of the patient, being the predominating influence; and it would seem probable that the direction of investigation should be influenced by these peculiarities. Thus, in acute and obviously infectious diseases, such as small-pox, more is likely to be gained by observing the condition of those who escape infection, although exposed to it, than by records of the multitude who are attacked; whereas, in phthisis to the contagion of which, if it exists, we must all be constantly exposed, and in the production of which, therefore, the fitness of the individual for its development must be the main element, information is most likely to be gained by inquiry into the surroundings of certain groups of cases, where, as sometimes happens, a series of individuals successively occupying the same position one after the other succumb to tuberculosis—where, in fact, without exposure to any special risk of infection, the disease has appeared in great excess of the ordinary rate. I would suggest, however, that, as infectious diseases form a distinct group, they are likely to be influenced by some common cause, that there is probably some agency common to them all by which that lowering of vital resistance is produced which allows bacteria to develop within the body and involve it in disease.

Much has been learned lately about the nature of dust, and it has been shown that the floating particles in the air of our towns consist chiefly of living matter, micro-organisms, germs, not necessarily germs of disease, but of fermentation and decomposition, that decomposition which comes to all when they die. But these germs, like vultures, do not always wait for death, but gradually pervade our bodies while alive, and as our vital resistance grows weaker ultimately, by sheer numbers, gain the mastery. After any slow death bacteria are found so universally throughout the body that it is obvious that their germs must have spread themselves through the tissues during life, and I have repeatedly been able to demonstrate the existence of bacteria in the blood of persons seriously enfeebled by various diseases. If thus we are being constantly assailed by organisms to which we must ultimately succumb, and if we only keep them off by virtue of that power which all healthy living

<sup>2</sup> Tyndall: Floating Matter in the Air.

tissue possesses of resisting the growth of other living tissue within it, which is, in fact, one of the chief signs of its vitality, it is obvious that the more this vital resisting power is used up against ordinary germs of decomposition, the less will be left to withstand the development of the more special micro-organisms which are concerned in the production of disease. It seems fair, then, to believe that if we so arrange our lives that we shall commonly eat partly decomposing food, drink bacterial water, and breathe germ-laden air, even although neither the food, nor the water, nor the air contain anything which is capable of producing disease, we shall so exhaust and use up, if I may so say, the vital resistance of our tissues that, although we may still appear in good health, but little power may be left to us of resisting the development and multiplication within our bodies of any disease germs which may come across our path. These views as to the importance of the preceding condition in permitting the development of germs into disease are strengthened by the recent discovery of the bacterial origin of tubercle; for here we have an instance in which the contagion habitually passes over the strong to attack those who are fitted for it either by constitution or by preceding disease, or by reducing surroundings, and even when it has picked out a feeble member of the flock and attacked such an organ as the lung, is usually impotent against those portions whose functional activity is greatest, and is prone to affect those in which renewal of air and removal of exfoliated epithelium are least perfectly performed, such as parts which have been inflamed or tied down by previous thickening of the pleura, and especially the comparatively unused apices of the lungs. When we see the chest of a phthisical patient covered with patches of cloasma, the thickened and unremoved epithelium infiltrated by the spores and mycelium of the micro-organism *furfur*, we carry the mind's eye inwards and think of the apices of the lungs and the similar processes going on within them, their air cells, little moved by the feeble respiratory efforts of the patient, gradually plugging up with exfoliated epithelium matted together by the growth of tubercular bacilli, which, although carried in far greater number into those portions of the lung whose functional activity is greater, have only been able to take root in the half-dead epithelium of the stagnant apical air cells. All these thoughts put one more in sympathy with those who aim at warding off infectious disease by general improved sanitation, rather than with those who try to keep it at bay by isolation and quarantine. One cannot help seeing that if these latter do not combine with their efforts to stamp out disease by isolation of the germ-producing patient, such measures as shall in the meantime diminish the receptivity of the people, their fitness for breeding within them these germs of disease, the only result will be that some time or other the contagion will break through the quarantine, and run riot in a universally susceptible population. Let us, therefore, while earnestly studying the micro-organisms, which are the essential causes of the whole class of infectious diseases, also investigate and search out the conditions of body under which they are capable of developing within the animal frame, trusting that we may so be enabled to find some means of rendering ourselves unfit breeding grounds, at any rate for those which are least virulent, and hoping that the same measures which do this may so far diminish our receptivity for the others as to make their attacks less frequent and less fatal.

## ACUTE CONJUNCTIVITIS CAUSED BY THE ELECTRIC LIGHT.

By W. C. ROCKLIFFE, M.A., M.D.

So far as I am acquainted with our English literature and periodicals, I am not aware that the effect of the electric light on the eye as producing acute conjunctivitis has been mentioned. The following case being the first I have met with, may therefore be of interest to the readers of THE LANCET.

A. B—, aged twenty-eight, was recently engaged in placing Siemens' electric light in the old part of the town, and, together with his fellow-workman, adjusting the carbon points of a lamp with 3000 candle power without coloured

glasses, which he informs me are always supposed to be worn during this portion of his business. As an almost daily occurrence the brilliancy of the spark causes more or less paralysis of the retina, or, to quote his own words, "he rarely is able to perceive the people walking on the footpath when descending the ladder from adjusting." Although this effect soon passes off, on this particular occasion, as he regained his power of vision (in about fifteen minutes), it was followed by rapidly increasing lachrymation, photophobia, pain and swelling of the lids, the whole symptoms being developed in thirty minutes. Having suffered from many slight attacks of a similar nature, he applied cold water, which previously had relieved him; but the pain and swelling increasing, I saw him the following day, apparently having suffered intense agony during the night. The lids of both eyes were very hot, red, swollen, and brawny, and level with the superciliary ridge, the swelling extending some little distance upwards over the forehead. The pain was most acute in and around the eye. On raising the lids (which was a very difficult operation, the photophobia being so very intense) a considerable amount of lachrymal fluid gushed out. The conjunctival vessels were exceedingly large, and the eyeball a brilliant scarlet; cornea clear. All these symptoms yielded to a brisk purge and lead lotion in forty-eight hours. His fellow-workman was similarly affected, but to a less extent.

As a considerable heat is thrown out from the lamp, it would be interesting to know whether these symptoms were caused by the brilliancy or radiant heat.

## NEW SPLINT-REST FOR SYME'S AMPUTATION.

By HENRY A. LEDIARD, F.R.C.S. ENG., &c.,  
SURGEON TO THE CUMBERLAND INFIRMARY.

THE accompanying woodcut represents a splint-rest which has been made for me by the infirmary joiner under the direction of Mr. A. Proffit, our house-surgeon at present. I have remarked that the ordinary straight backsplint, although most valuable in many amputations, fails to give support, if necessary, to the heel-flap in Syme's amputation. I allude to cases where the stitches are subjected to strain, and to cases where union of the flaps is delayed from some cause, and where adhesive plaster is employed after the stitches have been taken out. Again, in the usual dorsal position of the body after Syme's amputation, the cut end of the tibia tends to project somewhat from the drooping of the heel-flap, which is sometimes more bulky and heavy than at others, according to the nutrition of the patient and amount of tissue

available. I have lately tried the effect of a wooden splint so shaped as to fit the end of the stump and support its side and end. In order to promote drainage and to relieve tension, my old master, the late lamented Professor Spence, was in the habit of placing his Syme's amputations upon their sides and bending the knee. The discharge would thus drain through the outer angle of the flap, near where the tip of the external malleolus had been. This is an excellent method in some instances, if the lateral posture is tolerated, but the stump has occasionally a tendency to slew round, and to require readjusting with plaster. I consider, then, that the splint-rest figured will afford another step towards that rest and freedom from pain so essential in the treatment of wounds, which Hinton and Callender both taught and practised.

There are some Syme's amputations which do not require a thought from the moment of the completion of the operation, even strapping after removal of the stitches being wholly unnecessary; but it is not so in all, and whether the latter are treated with Listerism or the open method, I think that in a few cases my splint will be found serviceable. It will be observed that the splint is hollowed for the calf, as well as shaped for the stump end.

Carlisle.

## NEW AURAL FORCEPS.

BY GEORGE ABBOTT, M.R.C.S.,

SURGEON TO THE CENTRAL LONDON OPHTHALMIC HOSPITAL, ETC.

FOR some years I have used an improved form of ear forceps, made for me by Messrs. Maw, Son, and Thompson, which I have found very convenient and useful for the various purposes for which such an instrument is required; and I therefore now bring it before the notice of the profession. It is much lighter than any I have yet seen, and from its peculiar form it can be applied even through a good-sized speculum. When in use it lies along the sides or floor of the canal, therefore it interferes but little with the axis of vision and facilitates the removal of anything the operator may desire. With it I have frequently removed plugs of hard cerumen which I had failed to dislodge with a syringe, and which otherwise must have waited until they had been softened by the application of some alkaline solution. If the points are gently insinuated down the sides of the meatus, slight traction is generally successful in promptly removing the whole mass and without causing the patient any discomfort. Though weak and acting at a mechanical disadvantage, the instrument is strong enough for the removal of foreign bodies which it is thought advisable to remove in this way, for it is certain that powerful instruments or much force is seldom necessary; indeed, as a rule, they are not only awkward but mischievous.

## UNIVERSITY COLLEGE HOSPITAL.

PYELITIS (TUBERCULAR?) WITHOUT VESICAL DISEASE;  
CONSTANT VESICAL PAIN REMOVED BY DRAINAGE  
OF THE BLADDER THROUGH A PERINEAL  
APERTURE; REMARKS.

(Under the care of Mr. BERKELEY HILL.)

IN certain cases of pyelitis, usually of tubercular origin, most of the patients' sufferings are due to constant irritation of the bladder. The following is an instance of the relief which follows continual drainage of that organ through a perineal fistula containing a tube wide enough to permit of immediate evacuation of the irritating pus and urine as they arrive from the ureters. Drainage of the bladder by cystotomy has been occasionally employed for thirty years by surgeons in Europe and in the United States to cure obstinate cystitis,<sup>1</sup> and attention has lately been again drawn to the expediency of opening the bladder for the purposes of searching its interior or of draining it in cases of obstinate cystitis or of severe pain in the bladder.<sup>2</sup> In the case about to be related drainage was obtained without dividing the neck of the bladder itself. The importance of this point was in-

sisted upon by Sir H. Thompson in the paper of which the title is appended.

H. H.—, aged thirty-two, was admitted into University College Hospital a second time on Oct. 12th, 1881. In 1879 he had been an out-patient under Mr. Godlee's care, suffering from painful, very frequent micturition. The pain was referred to the symphysis pubis, and was relieved by voiding urine. But it recurred every one or two hours, or as soon as one or two ounces of urine had collected. The man was pale and meagre, but otherwise free of objective symptoms. The lungs were clear; the urine acid and clear, and free of albumen; the urethra of normal width; the passage of a sound over the prostatic part caused a sharp burning pain, but the bladder otherwise indicated nothing abnormal. The prostate was not enlarged or tender, nor could the vesiculæ seminales be distinguished. The corda, epididymes, and testes proper were quite healthy. No pains were referred to the loins at this period. Rest and anodynes reduced the pain, and the man returned to work. In 1880 he was admitted to the hospital with considerable increase of his former symptoms. He complained in addition of aching in the left loin. There was also tenderness in the left renal region. The urine, still acid, contained pus in considerable quantity. Exploration of the bladder gave the same negative result as before. Continuous drainage through the retained catheter was complained of; washing out and the use of various injections were therefore substituted. Some intermission of the pain followed this treatment, and the patient left the hospital. He was lost sight of until October, 1881. He then micturated every quarter of an hour, both by day and by night. Pain was felt for a few seconds after micturition along the penis, and aching pain had been constant for the last few weeks in the left loin, being worse during micturition. Since October 2nd he had had constant hæmaturia. At first quite purple, the urine became gradually light red; its condition on admission was uniformly coloured throughout the flow. There was also much pus in the urine, and it was ammoniacal. The patient had lost flesh greatly, but was free from cough and night-sweats, and had never spat blood. There was some dulness of the right lung below the clavicle, and a few moist râles in the supra-pubic fossa. Careful examination discovered no morbid condition of the urino-generative organs, except the kidneys, and even when the patient was anaesthetised no lumbar tumour could be felt. After lying in bed a week the patient lost the blood from his urine for a short time; it then returned in the shape of clots. The fetor and pus continued. The passage of a large clot caused much pain; but, on the other hand, its exit left an interval of painlessness. During November the pain increased, and was often referred to the pubic region instead of the left loin, and occasionally to the right loin. The urine, in spite of regular washing of the bladder, remained foul, loaded with pus, and nearly always containing shreds of blood-clot. The patient rapidly lost strength; his temperature varied between 100° and 104°; his appetite went and bedsores appeared.

On November 30th the patient was etherised and his abdomen carefully explored, but without detecting a renal tumour. A staff for mesial lithotomy having been passed, the urethra was opened behind the bulb, and the finger passed into the bladder. No tumour, nor even roughness, could be distinguished on the mucous membrane, of which the whole surface was easily searched by the finger when the apex of the bladder was pushed downwards. A lithotomy tube was tied in. Immediate relief followed the operation, and the calls to micturate, which had been almost constant for many months, ceased at once. In a few days the lithotomy tube was removed, with the result of reviving the old penile and suprapubic pain and spasmodic desire to micturate. To prevent this, a soft rubber tube, just long enough to reach the interior of the bladder, and mounted with a shoulder at the perineal end, was introduced, and gave immediate relief. It was continuously worn for several months.

The patient's general condition steadily improved. His appetite returned, and he slept well, and soon his bedsores healed sufficiently to allow him to sit upright. This posture he found most agreeable, as it ensured the most rapid evacuation of urine. In a few weeks he could shuffle about the ward, wearing a woman's urinal. Though the patient gained flesh and strength, and was wholly free from pain for days together, his lumbar pain, now on one side, now on the other, returned for some hours occasionally. During these attacks the temperature would rise to 102° or 103° F.,

<sup>1</sup> The Medical Record of New York, June 12th, 1880, contains an excellent historical summary of thirty-two cases of cystotomy in the male, by Dr. Robert F. Weir.

<sup>2</sup> See papers read before the Medical and Chirurgical Society in 1882, by Mr. Reginald Harrison, Mr. Berkeley Hill, Sir Henry Thompson, and published in the Transactions.

its usual range being 97.5° or 99° in the forenoon and 100° or 101° in the afternoon. In February two short attacks of pyrexia with rigor drove him to bed for a few days. At these times 104° were reached. The urine improved somewhat; though always loaded with pus the putridity diminished, and even disappeared, so that it was sometimes acid as it escaped through the tube. The clots were also sometimes quite absent. The proportion of pus was generally about one-fifth of the whole bulk. In the latter end of March the bladder had contracted so much that when injected it could not hold more than one ounce, and the tube was frequently thrust forth. The patient felt well enough to work again, and desired that his fistula might be closed, that he might be free of the constant dribble. His solicitations became so urgent and his readiness to submit to any operation so unmistakable, that he was etherised and his loins carefully searched with the hope of finding a renal abscess or dilated pelvis which might be drained directly through the loin. But this discovery was not made; and the probability that both kidneys were greatly affected determined the abandonment of any project for nephrotomy. The perineal tube was, however, removed, and the fistula allowed to shrink. As soon as the passage had narrowed considerably, the old frequent and painful micturition returned to such an amount that the patient begged the fistula might be again widened. This was done, and the patient regained his former ease. Nevertheless, henceforth he lost ground; he became too weak to sit up, and his attacks of pyrexia were more frequent. Early in June he was transferred to the Highgate Infirmary of the Central London Sick Asylum District. On June 21st Dr. Garman, under whose care he had been placed, very kindly wrote that acute meningitis had set in, of which he shortly died.

It is much to be regretted that the religious scruples of the patient's friends prevented Dr. Garman from making a necropsy, and so tracing the whole course of the disease. The evidence that the bladder was not itself the seat of the mischief was satisfactory. The pus was never "ropy," and the pain felt in that part was the same all through long before any pus appeared. Lastly, the whole bladder was easily searched by the finger, and any abnormal condition of importance could not have been passed over.

There are several practical points illustrated by this succinct history of tubercular disease, apparently at first, and for a long time, primary of the kidney, causing during its development these symptoms of reflex irritation of the bladder and suprapubic pains long before signs of renal disease became obvious. This case is an example of the possibility of nephritic disease being mistaken for vesical disease. Yet there was early strong probability of the affection being renal, and not vesical, from the absence of disease in the generative organs. Tubercle of the neck of the bladder (prostatic and peri-prostatic tissue) gives rise to suprapubic pain and painful and frequent micturition before cystitis is excited. But there is usually associated with it tubercular disease of the testes or vesiculæ seminales; also tubercle of the kidneys is usually secondary in point of time to that of the generative organs. With regard to the treatment, only palliative means could be adopted. The history shows how much distress may be removed by drainage of the bladder in cases of advanced renal disease, even where that viscus is not itself diseased. When washing out does not give relief, the patient may be brought at once, by drainage through a fistula, from a condition of constant suffering to one of complete ease. The danger that attends cystotomy when the kidneys are affected is avoided by the plan adopted in this case—viz., by limiting the incision to the perineum and to the membranous portion of the urethra, instead of carrying the cut to the bladder itself. In cases of pyelitis, prolonged retention of the tube is requisite; in those of cystitis, the cause of disease—tumour, enlarged middle lobe, &c.—can be removed or remedied when a few weeks of rest suffice to cure the cystitis; consequently, in such cases, the drainage need not last long.

In women stretching the neck of the bladder sufficiently to give room for removing the cause of cystitis is frequently practised. And the same procedure will give ease in cases of pyelitis where there is vesical irritation also. Mr. Hill referred to an instance of this which occurred to him a year or two ago. A young lady, a patient of Mr. Shoppee's, of Kentish-town, was long tortured by vesical irritation with pyelitis. Mr. Berkeley Hill and Mr. Shoppee divided the

neck of the bladder and dilated the urethra. No disease of the bladder was found, but the incontinence which was left by the operation for some time afterwards removed the constant straining to pass urine, and relieved the patient of pain until her death, several months later, from the general progress of the disease.

### ROYAL HOSPITAL FOR CHILDREN AND WOMEN, WATERLOO BRIDGE-ROAD.

PYÆMIA WITH ABSCESS AND HÆMORRHAGE INTO PLEURAL CAVITY; HEAD OF RIB AFFECTED WITH CORRESPONDING FACETS OF VERTEBRÆ; NECROPSY.

(Under the care of Dr. PARK.)

FOR the following notes we are indebted to Mr. T. Frederick Briscoe, resident medical officer.

M. A. B—, aged three, admitted into Alexandra ward July 3rd, died July 7th. First taken ill on Wednesday, June 28th, with pain in right shoulder and outbursts of crying. There was no knowledge of an injury, but the child had romped a good deal with the other children. The family history was good; no hereditary tendency. The father is a painter, and the children have access to the paint-pots, sleeping in the same room. There was one other child. The patient had had no previous complaints. Before arriving at the hospital two medical men suspected rheumatism. He lay with his eyes half open, and his tongue was thickly coated with a white fur. There was an offensive faecal odour. The child seemed to suffer much, for on being handled his cry was very distressing; he was well nourished, and has had no cough. There was a diffused glandular swelling just above the left clavicle that caused the patient to call out when touched. Opposite the middle of the spine was an inflamed boil. The chest showed complete dullness in front of the left side; the heart sounds were very distant, and only heard at times; apex beat could now and then be made out at ensiform cartilage. On the same side behind dullness was elicited, with tubular breathing, and there was a questionable pleuritic rub. The opposite side of the chest was also affected, there being dullness, with feeble respiratory murmur. The skin was hot and dry. Temperature 103.4°. Urine acid; specific gravity 1020; no albumen or sugar. The right wrist was slightly enlarged. Patient to have a cantharides blister 4 in. by 4 in. applied to the heart. Ordered milk and beef-tea; also two ounces of port wine.

July 5th: Motions passed, pale and greenish streaks.—6th: The patient had been crying on and off all night. There was gurgling in the chest behind, the swelling at the root of the neck increasing. Ordered three grains of Dover's powder every four hours. The swelling at the wrist was the same. The child lay with his eyes half open; if raised in bed the painful cry was very distressing. He was quieter on his side.—7th: Died quietly at 1.10 P.M. The temperature gradually fell till the 6th, when it went up to 102.8°, then dropped a degree and a half; before death it went up again to 102.4°.

*Necropsy.*—On removing the sternum, sanguinolent discoloured pus oozed up, and on further removal the upper third of the left pleural cavity was full of a dirty rusty-coloured pus; in the same cavity and partially attached to the walls of the chest was a large blood-clot about the size of a hen's egg. The heart was pushed over to the right side. The head of the first rib and the adjoining neck was bare of cartilage, and separated from its articulation with the bodies of the vertebræ, which had also their facets bare of cartilage. The posterior third of the corresponding intercostal space was worm-eaten. Pus ran down beneath the tendinous structures close to the spine and also burrowed amongst the muscles of the back, and upwards into the neck. There were pleuritic adhesions on the right side, and a slight effusion. The pericardial cavity contained an excess of fluid. Disseminated through both lungs were pyæmic patches of the size of beans and peas, but mostly the latter. There was no fracture of ribs, and on minute examination no bloodvessel could be found ruptured to account for the hæmorrhage. The enlarged wrist on incision showed the parts to be healthy. The solitary glands with Peyer's patches were picked out in black spots as if there were some deposit there. Besides an excess of injection of a few of the valvule conniventes, the rest of the abdominal

contents were healthy, as far as the unaided eye went. There was a slight staining of the dura mater between it and the vertebrae, opposite the disease spot.

## THE MANCHESTER WORKHOUSE HOSPITAL.

### CASE OF ABDOMINAL ANEURISM RUPTURING INTO THE PSOAS MUSCLE.

FOR the following notes we are indebted to Mr. W. E. Bailey, M.B.

P. G.—, aged forty-two, labourer, married, was admitted on May 23rd, suffering from pain in both hips, back, and left side. His general appearance was that of a well-nourished man of muscular build. His previous health had been good until two years ago, when he fell from a scaffold, alighting on his back. After this accident he experienced severe pain of a gnawing character in the back and left lumbar region. The pain was constant, but subject to many severe exacerbations. Any attempt at progression increased its severity. No history of syphilis or chronic alcoholism.

On examining the seat of pain no swelling could be detected, but the dulness in the region of the left kidney was abnormally increased in area, extending horizontally from the vertebral column behind to a point midway between this and the middle line in front, and vertically in the mid-axillary line from the ninth rib to a couple of inches above the crest of the ilium. Pressure over the area of dulness caused great pain, and when in the recumbent position the patient experienced much difficulty in turning from side to side, during which effort the spinal column was kept quite rigid. Heart and lungs free from organic disease; pulse regular, quick, and moderately strong; anorexia; temperature normal; urine healthy. Palpitation and percussion revealed no other abnormal peculiarities in other regions of the abdominal cavity. Turpentine stupes were applied over the painful part, and one grain of opium was given at night with great relief.

Patient appeared to be doing well until the 29th of May, when he again suffered from very severe gnawing pains, which were relieved for the time by the application of turpentine stupes. The following evening the pain recurring in the left lumbar region, a hypodermic injection of amyl nitrite (1 in 10) was administered and followed by almost immediate relief. Patient slept well during the night, and expressed himself as feeling much better the following morning, the pain having entirely disappeared. About this time (June 1st) the patient was placed on low diet and large doses of potassium iodide, absolute rest in bed being enjoined. He seemed to be progressing satisfactorily until the evening of June 21st, when he became suddenly much worse. Mr. Voisey, the assistant medical officer on duty, being summoned, found the man suffering from excruciating pain in the left side, urgent dyspnoea, blanched countenance, body bedewed with a cold and clammy perspiration; pulse small, quick (140 per minute) and easily compressible; his facial expression was indicative of great suffering, and his general appearance gave the impression that extensive internal hæmorrhage had occurred. On examining the seat of pain, a slight swelling could now be perceived, characterised by expansile pulsation and dulness on percussion; but there was total absence of anything approaching the nature of a bruit. Slight pressure over the tumour gave great pain; the area of dulness was much increased, its boundaries being as follows: above, seventh intercostal space; below, crest of ilium; in front, a line drawn vertically from the anterior fold of the axilla to the crest of the ilium; and behind, the vertebral column. Over the rest of the abdomen the percussion note was normal, and remained so in whatever position the patient was placed. One grain of opium was ordered to be taken every three hours. The following morning (June 23rd), after a moderately good night, his general condition seemed slightly improved, and on examination the area of dulness had not further increased, but the expansile pulsation of the tumour was much more distinct, though still, on auscultation, no bruit could be detected. The radial pulse was almost imperceptible; the pain had abated in severity. The patient continued in this state until 9.45 the same evening, when the breathing suddenly became gasping, and he died a few minutes afterwards from syncope.

*Necropsy, seventy-two hours after death.*—Surface of body

very much blanched; lips pale. On opening the abdomen the peritoneal cavity was found to contain a large quantity of blood-clot, by far the larger mass having gravitated into the cavity of the pelvis. In the left lumbar region was a large fluctuating tumour, which had displaced the intestines and left kidney forwards, and to the right. Extending upwards it had encroached upon the left lung, and crossing the middle line a pouch as large as a hen's egg was situated in front of the right kidney. On cutting the peritoneum over the tumour the left kidney was found pushed forwards by a mass of coagulated blood effused between its posterior surface and the sheath of the psoas muscle; after removing this clot the psoas was found abnormally large and misshapen, and on incising it a large quantity of clotted blood, macerated muscular tissue, and laminated fibrin escaped. A horizontal incision was then made through the tumour, prolonged a cross the middle line to the small tumour already mentioned as situated in front of the right kidney; both the cavities communicated with the aorta by means of large openings. There was no trace of the posterior surface of the aorta, and the limiting sac of the aneurism behind was formed solely by the bodies of the first and second lumbar vertebrae, which were much eroded, and the intervertebral disc standing out between them unaltered. There was an irregular rent in the peritoneum at the junction of the sac of the aneurism of the left side, with the healthy part of the aorta through which the fatal gush into the peritoneal cavity must have occurred. Aorta studded with atheromatous patches; other organs healthy, but excessively anæmic.

## Reviews and Notices of Books.

*Nouveau Dictionnaire de Médecine et de Chirurgie Pratiques.* Directeur de la Rédaction, Dr. JACCOUD. Tome XXXII. Pp. 796. London: J. B. Baillière, Tindall, and Cox. 1882.

THE principal articles contained in this volume are, Rougeole, by M. D'Espire; Saignée, by J. Ballet; Salicilique Acid, by MM. Prunier and Ory; Salivaire (appareil), by Delorme; Salivation, by Letulle; Sang, by MM. Danlos and Vibert; Sanitaire (régime), by M. Proust; Sarcome, by Heurtaux; Scarlatina, by Picot; Sciatique, by M. Homolle; Sclerème, by M. Balzer; Scorbut, by M. Rey; Scrofule, by M. Brissaud; Scrotum, by M. Jullien.

A large space is of course devoted to the blood by M. Danlos, which, in accordance with the excellent plan adopted in this dictionary of practical medicine and surgery, is considered in all its bearings under one head. Its physical properties are first considered, and then the phenomena of coagulation (the theory of coagulation is taken up at a later period). The corpuscles are next described, commencing with the red, and giving their size, form, chemical reaction, number, and structure. The question of the existence of an envelope M. Danlos does not regard as absolutely settled, though the balance of argument is against its presence. He has nothing to say in respect to the colourless corpuscles of Norris, Bizzozero, and Hart. The several modes of procuring blood-crystals are given, and he then proceeds to give the spectrum of oxidised and deoxidised hæmoglobin. A good account is added of the replacement of oxygen by other gases, as CO, NO, C<sub>2</sub>H<sub>2</sub>, and CNH, which last M. Danlos agrees with Gamgee in regarding as doubtful. The chemistry of the plasma follows, and it is impossible to read this without feeling how imperfect our knowledge is of the entire subject of the organic constituents of the blood, and how much remains to be done for pathology by modern chemistry, the variations in the kind and quantity of albuminous compounds in particular opening up a wide field for research. M. Vibert contributes a short but good article on the medico-legal aspects of the blood.

The article on Sarcoma by Heurtaux summarises very fairly our present knowledge of this form of disease. He recognises three kind of cells: round, fusiform, and giant, the predominance of one or the other of which confers its special characters on the growth. He does not admit the existence

of free nuclei. The cells in direct contact with each other or separated only by a little soft amorphous matter, and more or less numerous vessels, compose the whole mass of the tumour, and he describes the different forms of sarcoma under the headings given by Cornil and Ranvier, of encephaloid, fasciculated, myeloid, osteoid, neuroglie, angiolithic, mucous, lipomatous, and melanotic. The fasciculated form is our recurrent fibroid, the neuroglie is the glioma of Virchow, and the angiolithic is the psammoma of the same author.

As we advance in life many of the tissues harden and condense, a process of induration affects the internal organs, the functions of which are gradually performed with less and less activity, and by degrees the natural structures are to some extent replaced by connective tissue. In various forms of disease a similar but more rapidly progressive change is observed, to which the term sclerosis is applied. In investigating the phenomena attendant upon this change French observers have been prominent.

Kiernan, indeed, in this country was the first to point out the alterations which occur in chronic interstitial inflammation of the liver, and paved the way for an extensive generalisation of the process; but we are indebted to Esquirol and Calmeil for much original information in regard to the changes occurring in diffuse periencephalitis; to Duchenne for many important facts bearing on locomotor ataxy; and to Charcot for his observations on visceral cirrhosis. The microscope shows that sclerosis may be divided into two periods, one in which there is an immense development of embryonic cells with concomitant extension of vessels, and a second period in which either the vessels disappear and the tissue formed by the cells becomes hard, firm, and contracted, leading to the atrophy and disappearance of the normal tissue, whilst the new tissue itself, by further contraction, may ultimately become greatly reduced in bulk, so that a kidney, for example, suffering from advanced sclerosis may weigh less than an ounce; or, if the vascular supply be not interfered with, hypertrophy instead of atrophy may be seen, as in elephantiasis Arabum and hypertrophic cirrhosis of the liver. The etiology of sclerosis is that of chronic inflammation generally, and M. Balzer, by whom the article is written, divides the various forms primarily into diffuse, systematic, specific, and neoplastic sclerosis. In the diffuse form he includes traumatism and phlegmons of all kinds, in the systematic form he includes interstitial nephritis, cirrhosis of Laennec, and perivascular sclerosis, with passive congestion—in fact, all those forms which follow primitive interstitial inflammation, as well as those which are consecutive to parenchymatous lesion. His group of specific sclerosis embraces those that are of parasitic origin, as lepra, tuberculosis, syphilis, and those resulting from paludism, whilst the neoplastic sclerosis are represented by fibromata and scirrhus. Each of these forms is briefly described.

*Manual of Pathological Histology.* By CORNIL and RANVIER. Second Edition. Re-edited and Enlarged. Translated, with the approval of the Authors, by A. M. HART. London: Smith, Elder, and Co. 1882.

**PATHOLOGICAL** students are too familiar with MM. Cornil and Ranvier's manual and appreciate it too highly to do else than cordially welcome this translation, which has promptly followed upon the appearance of the French edition. For it is no exaggeration to say that the publication of the first part of the manual, thirteen years ago, was an event that did a great deal to stimulate careful histological study in morbid anatomy. The volume that then appeared dealt chiefly with tumours, and it supplied a want not met by the magnificent (but unfortunately never completed) masterpiece of Virchow, where histological details were somewhat subordinated to the wider bearings of the subject. In the present new edition this first volume comprises not only general pathology, but also deals with the lesions of the

tissues, the second volume, the appearance of which, we trust, will not be long delayed, being devoted to the special organs.

The great merit of Cornil and Ranvier's book has always seemed to us to lie in its eminently practical character. The authors deal but slightly with theoretical questions, and when they do venture upon such ground their deliverances are far less sound than many other treatises. But in the work of descriptive histology, and the correct interpretation of the characters presented by tissues and organs when examined by the microscope, they certainly excel; and many an investigator owes a debt of gratitude to these writers for having guided him aright in the pursuit of this branch of knowledge. The translator of this volume worked in their laboratories and has their particular sanction for the translation. The first edition was rendered into English by Drs. Shakespeare and Sims, of the United States, and they made several additions to the text and illustrations. But the present translation contains few such additions. Indeed, the work is sufficiently complete in itself, and it were a pity to deprive it of its characteristics by unneeded paragraphs.

In comparing this with the first edition we note several important changes, both in the sections devoted to normal histology of the tissues and in the purely pathological chapters. Moreover, the introduction of a chapter on the blood and several additions to that on diseases of the nervous system testify to the advances made in the science during the last decade. On the whole we may safely recommend the work as the foremost text-book of its class, and we are certain that it will now be widely studied by many to whom the original was a closed book.

## New Inventions.

### NEW SAFETY HYPODERMIC INJECTOR.

IN view of the frequent employment now made of hypodermic medication, and the costliness and trouble of the syringe generally used for the purpose, Dr. Ward Cousins, Surgeon to the Royal Portsmouth Hospital, has introduced a cheaper and simpler instrument. It consists of an elastic measuring ball and an injecting needle; a boss on the latter serves for a handle in its introduction; the needle may be either fixed to the ball or jointed at the boss. The balls are made in various sizes, holding from one to twenty minims, so that if the right ball be selected an accidental overdose of the drug administered is impossible. The ball is charged by compressing the ball and allowing it to expand, while the point of the needle is immersed in the fluid to be injected. Dr. Cousins urges that a separate instrument should be used for every drug, and also for every patient. We doubt whether this "safety" injector will replace the syringe now in use; but in cases where it may be considered necessary to leave the administration of hypodermic injections to nurses or patients' friends, this injector will be found a great improvement upon the syringe. The apparatus is made by Messrs. Lynch and Co. of Aldersgate-street.

### HUXLEY'S SUPPORT AGAINST RIDER'S SPRAIN.

THIS apparatus consists of a firm band fitted with a pad impinging on the usual seat of injury. The band is firmly buckled so as to secure pressure on the very highest part of the thigh. The holding it securely in this position has been the great difficulty, but this is effectually accomplished by Mr. Huxley's arrangement of support by a pelvic band, which renders the important thigh arrangement absolutely immovable. The drawback to the figure-of-8 contrivance, recommended by many surgeons, is that it is necessarily relaxed when in the riding position, and cannot secure the direct support realised in all positions by this band.

# THE LANCET.

LONDON: SATURDAY, AUGUST 26, 1882.

STRENUOUS as have been the efforts made to establish for syphilis a position in the domain of bacterial pathology, they have at present met with but scant success. Nevertheless, all analogy points to the probability that syphilis, like leprosy and so many acute diseases, depends upon an organised contagium, and the proof of it cannot be long delayed, although the observations which exist at present are too fragmentary and varying to be allowed very strong weight. KLEBS, indeed, has described bacteria in freshly extirpated primary indurations, but could not succeed in demonstrating the presence of such organisms in the secondary gummata. AUFRECHT found micrococci in the juice from a condyloma, and now a further link in the chain of evidence has been supplied by BIRCH-HIRSCHFELD, of Berlin, who states that he has found micro-organisms with constancy in gummatous ulcers. The growths were for the most part of recent date. The bacteria were most abundant at the limit of the granulation tissue towards the part which had undergone granular disintegration, and passed into the periphery of the latter—i.e., into the central caseating mass. They could be most readily demonstrated where the round and fusiform cells of the granulation tissue were less densely aggregated. As a rule, the bacteria were absent in the finely fibrous part of the syphiloma, and they could never be discovered in the syphilomata which had undergone complete cicatrisation.

Whenever the bacteria were free in the tissues, they were constantly aggregated into small colonies. When these were examined with a moderate magnifying power, they often gave the impression of roundish micrococci, but in many colonies they were seen to be small rods; under a higher magnifying power the roundish objects were discovered to be distinct rods, but very short, not more than a micro-millimetre in length, relatively thick, and with rounded extremities. While it seems probable that the round appearance of the elements is in many instances merely an optical illusion, yet in some colonies groups of distinct micrococci could be seen. They were especially conspicuous in the tissue at the base of a syphilitic ulcer of the intestine. Near each aggregation of minute rods there were also, in many preparations, groups containing rods of larger size, three or five micro-millimetres in length. These lay in long fusiform aggregations; transitional forms were seen between the larger and smaller rods. The larger were slightly curved, with rounded extremities, and frequently presented knob-like swellings. No distinct segmentation could be seen, but merely indications of the process. In some instances intracellular bacteria were found, especially in a gummatous tumour of the suprarenal body in a large liver gumma, and in one in the lung in a case of inherited syphilis. The cells which contained bacteria were round, oval, and spindle-shaped elements of the granulation tissue. They were often spread over a large area of the section, although they never

equalled in number the cells which contained no micro-organisms. The rods in the cells were short and thick, resembling perfectly those of the smaller aggregations. Some cells were entirely filled by them; in others the organisms were arranged in a ring in the periphery of the cell.

The free aggregations of bacteria were detected in a tolerably simple manner. Sections from organs which had been hardened in absolute alcohol were laid for a short time in vinegar, and then examined in glycerine. The masses of bacteria in the translucent tissue could then be readily seen, conspicuous, in consequence of their strong refracting power, among the other clear and swollen elements. Fuchsin was found to answer best for colouring the bacteria. The section was placed for a short time in a moderately concentrated watery solution, obtained by diluting an alcoholic solution. The water was then removed from the section by means of alcohol. It was cleared by oil of cloves, and examined in Canada balsam. The aggregated bacteria, and still more those in the cells, were then conspicuous by their red colour, which was, however, destroyed by the addition of concentrated acetic acid. Twelve gummata from seven cases were examined in this way: one of the brain, two of the lung (one of them from acquired and the other from congenital syphilis), five of the liver, one of the suprarenal body, one of the wall of the stomach, and two of the intestine. In all the bacteria were found, although their number presented considerable variations, and in some only the smallest, micrococcus-like rods could be seen. With these, tissues obtained in a fresh state from living subjects were also compared. These were taken from three condylomata, an indurated chancre, and a papule from a papular syphilide. Sections were made with a freezing microtome, and were cleared with acetic acid. In all were found the same masses of small, short, refracting rods. They were most abundant in the one broad condyloma, in which they lay in the cells of the Malpighian layer, and in the connective tissue of the papillary bodies. Lastly, the blood of a patient suffering from a syphilitic roseola was examined, but no bacteria could be found in it.

The micro-organisms found by KLEBS in the induration tissue of a chancre, granules and short thick rods, correspond closely in character with those now described by BIRCH-HIRSCHFELD; but the latter could see no individual movement of the bacteria, such as was described by KLEBS. The micrococcal objects found by AUFRECHT are also, perhaps, identical with the smallest rods, with which they correspond in their ready and deep colouration by fuchsin. Where these organisms are found in morbid structures which have lost their covering of protective epidermis, it is obviously possible that they may have entered from without, and may thus have no specific character or special pathological significance. But this objection does not apply to the presence of these bacteria within gummata in various internal organs, a fact which renders it highly probable that they are, in fact, the elements, or, at least, the bearers, of the syphilitic contagium. It is only by accumulated evidence of this character that the organised character of the syphilitic virus can be rendered probable. A rigid proof, in such a case, can only be furnished by the cultivation of the organisms out of the body, and the production of the

disease by their inoculation. The obvious difficulties in the way of such verification render it doubtful whether this rigid proof will ever be forthcoming.

THE notification of infectious disease is one of the great questions that must be settled. One human being can scarcely do a more cruel or a more unjust thing to another than convey to him by neglect an infectious disease. In this country we are worshippers of liberty; but true liberty has its limits, and anyone who claimed the right to transmit to his neighbour or his neighbour's child scarlet fever or the hideous small-pox, would find himself in the company of anti-vaccinationists and other fanatics. The facts which come to light every now and again of the transmission of such diseases by carelessness or concealment, are making a strong impression on the public mind, which, in the case of thirty-one towns, has grown into a demand for a law requiring the notification of infectious diseases. This demand is at first sight so reasonable, that there is great danger of its being made too abruptly and without sufficient regard to all the objections and difficulties in the way, and without due consideration of the question upon whom this duty of notification shall rest. It is evident that there is some difficulty in the mind of the profession itself as to this question, and that some of those who assume to represent it have really not been doing so. Though the accuracy of some of the statements in a pamphlet entitled "The Relation of the Parliamentary Bills Committee of the British Medical Association to the Compulsory Notification of Infectious Diseases" has been called in question, it is tolerably clear that the Parliamentary Bills Committee, consisting largely of medical officers of health and other metropolitan members, have been under great delusions as to the feeling of the Association in favour of a system of notification by the medical man. The recent discussion in the Association, and the resolution proposed by Dr. MAHOMED, in which it ended, are proof of this. This resolution took the shape of an amendment on a proposal of Dr. LITTLEJOHN'S,—

"To decline to withdraw the approval which the Association has repeatedly expressed in favour of urging Parliament to make the notification of infectious disease generally compulsory, under such conditions as may appear to be, after due inquiry, best calculated to protect the public health."

Dr. MAHOMED'S resolution, ultimately carried, is as follows:

"That this meeting earnestly desires compulsory notification of infectious disease, but it wishes to express its opinion that the compulsion to notify should be placed upon the householder, as his duty as a citizen, and not upon the doctor."

It is gratifying to us to find the Association expressing so plainly the views we have always held on this subject—a desire for a system of notification, and the opinion that the duty and responsibility of notifying should rest with the householder. It is time that this duty and responsibility were duly brought home, by the education of law, to the mind of the said householder, who with an apathy that would always be criminal if it were not frequently associated with ignorance, often infects a whole connexion or neighbourhood. Medical men require no such education. They have no leisure to become informers. They are the servants of

the patients, not of the State. But though they are naturally unwilling to be made informers, or, as Dr. MAHOMED said, detectives, they will be true to their reputation of doing more in the way of preventing disease than all the rest of the public put together. They will be true to their duty to their clients, and give them timely information of diseases which have a terrible public interest, and which the client will have to report to the sanitary authority. In any legislation on this subject much will be gained by consideration of the medical practitioner, and by securing that he shall be in no way hurried. The diagnosis of infectious diseases is sometimes, even for days, a matter of difficulty. The initiatory symptoms of the most diverse diseases have a considerable resemblance to each other. Time must be given for the medical man to be perfectly satisfied in his own mind. Medical officers of health who do their work best have no difficulty in securing the co-operation of medical men. It will be so still more under a public system of notification, when the diagnosis of disease will have a new and a public importance. Only there must be no undue haste. The medical man will be entitled, more than ever, to ask for time to form sound conclusions before imparting them to those who will have to transmit them to the sanitary authority.

Dr. ATTFIELD'S presidential address, delivered to the members of the British Pharmaceutical Conference at Southampton on Tuesday last, contains much that is of interest to medical men. Pharmacy in every country has to perform high and important duties towards the State. As the handmaid of medicine, she must help us in our endeavours to cure the sick and maintain the health of the community. To procure drugs she must search far and wide, and must then take steps to distribute them to the consumers. As Professor ATTFIELD points out, this question of distribution is a very serious one. Very different agents perform this duty. There is first the pharmacist proper, who is not only a distributor but a manufacturer or compounder of the pharmaceutical preparations he distributes. Then there is the druggist who makes few if any compounds, trusting for their purity and efficiency to wholesale manufacturers. Third in importance as a distributor of drugs is the general practitioner of medicine who supplies an important demand, not only where pharmacists could do the work, but in outlying country districts remote from a druggist's shop of any kind. The distribution of drugs is also effected to some extent by shopkeepers other than druggists—by grocers, drapers, and such vendors—who admittedly know nothing about drugs, and who, except that they buy in bulk from the wholesale dealer or manufacturer, and retail in small quantity, sell the drugs in the state in which they are received. Lastly, drug distribution is in many countries extensively accomplished by the agency of proprietary medicines termed "patent," though only so-called nowadays in a *lucus a non lucendo* sense, the composition of most of them being a secret. Those compounds pass from the producer to the consumer, either by the agency of the retail dealer or through the post-office. The maker of the patent medicines may or may not be a person having knowledge of drugs, and may not even reside in the country in which his articles are sold, so that he cannot be held legally responsible for any harm they may

do. As an example of the enormous use of these preparations in this country, we are told that patent medicine stamp duty to the amount of £144,000 was paid last year, which is equivalent to at least a million sterling as the present annual payment by the British public for secret remedies.

THE Report of the State Board of Health for the Hawaiian Islands, after dealing with a serious epidemic of small-pox during the past year, contains an account of the leper settlements for the islands, and of their administration. Dr. G. L. FITCH speaks in terms of the strongest condemnation of the manner in which lepers, when discovered, are hurried off to the principal island settlement, and he regards the severity as entirely uncalled for. But he bases his opinion largely on the view which he holds, to the effect that leprosy is not infectious or contagious; that it is, in fact, a fourth stage of syphilis brought about by the ravages of that disease in a virgin race, amongst whom the poison was introduced about a hundred and fifty years ago. The people being of a thoroughly licentious character, syphilis had, according to Dr. FITCH, thoroughly permeated the community about sixty years ago; and then, owing to a special predisposition of race, the disease known as leprosy manifested itself as a stage of syphilis. He brings forward a series of arguments in favour of his views, one of these being that he never yet has seen a case of leprosy in which syphilis as an antecedent, either hereditary or otherwise, could not be made out. On the other hand, Dr. N. B. EMERSON very strongly combats these views; he entertains the opinion expressed in the Report on Leprosy by the Royal College of Physicians, to the effect that leprosy is a disease *sui generis*, and quite unconnected with any other affection. He shows that leprosy antedates syphilis by many hundred years; that in many races syphilis in its most aggravated and neglected forms prevails without a sign of leprosy; and that, though the Hawaiians were extensively diseased with syphilis before leprosy appeared amongst them, yet that a considerable minority, including lepers, are and have been exempt from that disease in any form. And, lastly, he holds that views similar to those promulgated by Dr. FITCH are full of peril, because of the influence they may have in leading to a sanitary policy which is likely to be destructive to health amongst such a population as that under consideration. Dr. EMERSON'S views are certainly those which are most generally entertained, and they are based on a wide experience of the disease in many parts of the world. They must also be held to justify some form of isolation for those attacked with this terrible disease. But nothing can, we think, call for action such as is described in certain parts of the report, and which has also called forth a protest by the Assistant Attorney-General of the kingdom. This gentle man describes how people supposed to have leprosy have been taken summarily from their houses by the police authorities, and have, without a moment's preparation, been ordered into boats, and conveyed across to one of the island settlements, where, as he says, they "are practically doomed to death." Some of these people were parents hurriedly taken from their children, some husbands removed from their wives, and this without even a chance of getting the clothing necessary to their change of abode, or of an opportunity of arranging their affairs. It is hardly

to be wondered at, under these circumstances, that slight attacks of leprosy are carefully concealed, especially amongst women, who can remain in their own homes, that treatment in the early stages is hence neglected, and that the disease spreads till, as Dr. FITCH says, it is to be found everywhere amongst the native population. It is, however, satisfactory to find that the principal settlement at Kalawao consists of some 5000 acres of fine pasture land, interspersed with woodland and valley, mountain and ocean, where the lepers find agricultural and other employments, and that they are unanimous in their testimony as to the excellence of the food provided for them by the State Board in their enforced banishment.

## Annotations.

"Ne quid nimis."

### THE PROGRAMME OF THE INTERNATIONAL SANITARY CONGRESS.

THE carefully devised programme of debate laid down for the International Congress of Hygiene which, as we announced last week, will meet at Geneva from the 4th to the 9th of September, conveys a very clear conception of the subjects to be discussed. General meetings will be held in the afternoon, while in the morning the Congress will be divided into sections. The first afternoon will be devoted to inaugural addresses, and the report on the prize of £100 offered by the Provincial Council of Turin for the best work on hygiene in rural districts. The second sitting will be rendered particularly attractive by the presence of M. Pasteur, who has promised a paper on "L'Atténuation des Virus." Dr. and Professor A. Corradi, of Pavia, will introduce a debate on the contagious nature of phthisis and its relation to questions of general hygiene. Dr. G. Varrentrapp, sanitary councillor of Frankfurt-on-the-Main, is to read a paper on what are termed "holiday colonies," an organisation peculiar to Germany, by which delicate town children are sent out for various periods into rural districts. As an appropriate local subject, Dr. H. C. Lombard of Geneva will open the fourth meeting by discussing the influence of mountain air in the treatment of disease, and among the list of speakers we note the familiar name of Dr. Paul Bert. Dr. W. Marcet will also speak. The work of the sections is far more elaborate. There will be in all five sections. The first, devoted to general administrative and international hygiene, will debate the prophylaxis of typhoid fever and the influence of alcoholism. Dr. A. Proust, who with Dr. Bert was a member of M. Gambetta's cabinet, will present to this section a study on the Mecca pilgrimage and its influence in spreading cholera throughout Europe, with respect especially to the epidemic of 1881. The spread of yellow fever, quarantines, the necessity of weekly rest, and, finally, the principles of sanitary administration in England complete the subjects of this section. Mr. Edwin Chadwick, C.B., and Dr. Acland, Professor at Oxford, are to introduce the last-named subject. In the second section, devoted to Military and Public Hygiene, Dr. Vallin, Professor of Hygiene at the Val-de-Grâce, and editor of the *Revue d'Hygiène*, has a very remarkable paper on disinfection. The elaborate summary given of this essay in the programme shows that the learned professor has entirely adopted English ideas on this all-important subject, though these principles have so often been qualified in France as exaggerated and impracticable. Dr. Vallin now advocates compulsory declaration of infectious diseases, isolation, disinfection by fumigation, by dry heat, and destruction by fire, and within the room itself, of especially

contaminated objects. This—for the Continent—most progressive paper will be followed by another on the disinfection of persons. It would, however, take too much space to enumerate all the subjects that will be discussed in the sections, these embrace the question of cemeteries and cremation, medical and sanitary statistics of every description, the effect of bad shoes on the effective strength of armies, sanatorium for strumous children, hospital barracks, the prophylaxis of diphtheria, the disposal of sewage, the ventilation and warming of dwellings, industrial poisons, the report of the International Society for the Improvement of Drinking Water, putrefaction, the effect of schools on the health of children, the prophylaxis of hydrophobia, and, finally, a very interesting paper by the eminent architect, M. Emile Trélat, on the advantages and disadvantages of a permeable surface to the walls of dwellings. With so tempting a programme before them we trust that a large number of English sanitary reformers will assist by their counsel and presence this international effort to improve public health.

#### THE REPORT OF THE ROYAL COMMISSIONERS.

WE are at length in possession of the Blue Book of the Medical Acts Commission, including the report of the Commissioners appointed to inquire into the Medical Acts and Minutes of Evidence, Appendices, and Index. Thus, for the sum of five shillings, members of the profession, on application to Her Majesty's printers, Messrs. Eyre and Spottiswoode, can receive a valuable body of evidence on the working of our present examining bodies and of the Medical Council which cannot be had in any other form, and which is likely to constitute the basis of new and much needed legislation. We shall take an early opportunity of commenting on the evidence of the forty-two witnesses examined by the Commission, only in the meantime expressing satisfaction at the fact that the volume is issued in time for consideration before the pressure of the autumn session begins. In the absence of Lord Spencer, this duty will mainly fall on Mr. Mundella, who may be trusted to take a sensible view of the means for diminishing the absurd number and the competition of the licensing bodies, increasing the efficiency of the Medical Council, and making it more easy for the public to distinguish between qualified and unqualified practitioners of medicine.

#### THE TYPHOID FEVER EPIDEMIC AT BANGOR.

WE regret to learn that during the past two weeks the epidemic at Bangor has shown signs of rapid extension, and that considerable public anxiety prevails in consequence. It is, however, a matter of common experience that an enteric fever outbreak, commencing by means of water-pollution, makes later on, and this even when the original source of pollution has been stopped, rapid extension in localities where faulty sewers and house-drains exist. As we pointed out last week, these are precisely the conditions prevailing at Bangor. The houses being placed, by means of drain-pipes, in direct communication with sewers now containing the specifically poisoned fever evacuation, their occupants must of necessity be exposed to the influence of the poisoned drain air. The disconnexion of all house-drains, so as to secure an ample air-break between the house and the sewers, should be proceeded with without delay. It is alleged that sufficient skilled men cannot be obtained for this purpose, but if the sanitary authority were to appoint one or more skilled persons to supervise ordinary labourers, the work would, after the first start, not be found one of difficulty. At a meeting, presided over by the Bishop of Bangor, the question of hospital provision was raised. Quite apart from the boon which such provision would afford to the sick, it

would be an immense gain to the town if the sick could be aggregated in a place where they would be under efficient supervision, so that their excreta should no longer find their way into the faulty town sewers. The sanitary authority has ample powers to make such provision, and in the interests of the health of the community it should not be delayed. Hospital tents have been referred to as desirable. With regard to this, experience has shown that with well-constructed double-walled hospital marquees, such as are provided by Messrs. Pigott Brothers, of Bishopsgate-street Within, the best results may be expected; and, as the summer season is passing away, it may be well to recall the satisfactory results which followed on the heating of these tents by means of hot-water pipes when they were used last year by the St. Pancras vestry.

#### THE RAPIDITY OF VISUAL PERCEPTION.

M. CHARPENTIER has endeavoured to determine (as others have previously done) the interval which elapses between the appearance of a light before the eye and the production of a signal by the subject as soon as the light is perceived. In the course of these experiments, he ascertained whether the interval is the same for the central and peripheral parts of the retina, whether exercise is capable of modifying the duration, and whether such modification produced by exercise is or is not limited to the part exercised. In these experiments, the eye, fixed in the centre of a perimeter, was directed towards the bottom of a large box lined with black, in which a hole was made, a square centimetre in size, opposite a well-lighted window, but usually closed by a black metal plate. This plate was kept in position by an electro-magnet, so that it fell immediately as soon as the circuit was broken, and the interruption was also indicated by an automatic registration on a revolving cylinder. This marked the moment at which the window was exposed. The pressure of a button, the moment the light was seen, re-established the circuit, which was also marked on the registering cylinder. The interval between the interruption and restoration of the circuit, measured by the vibrations of an electric chronograph, indicated the time necessary for the individual to perceive and to signal the light. This perception-interval, "personal-equation" (which M. Charpentier calls by the somewhat misleading term of "duration of luminous perception"), is found to vary for the same person and under the same conditions, the longest interval being about double the shortest. But the mean of a series—say ten—is found to be the same for the whole period of the experiment. In the case of the author, for instance, with daylight, the average period was found to be .13 sec. The interval varies also, in different persons, from .09 sec. to .15 sec. Under normal circumstances the interval is the same for each eye. It is notably augmented by another cerebral occupation imposed on the person during the experiment. If the subject talks, for instance, or listens attentively to a lecture or a conversation, the latent interval may amount to .04 sec. or .06 sec. more than when all his attention is concentrated on the observation. The interval is always greater for indirect than for direct vision, and it is the longer the farther the point stimulated is from the centre of the retina. At first the difference is very considerable, amounting to as much as .07 sec.; but it lessens gradually during a long course of experiments, and at the end of six weeks did not in one case exceed .02 sec. The difference cannot, however, be altogether removed by exercise, which also lessens the interval for direct vision. Having ascertained that the interval was the same in each eye, M. Charpentier made, every day during six weeks, fifty observations at two points, one at the centre and another 80° distant from the centre in the outer part of the visual field. At the end of

this time he was in a position to appreciate the influence of exercise on these points in the other retina, and also on other points of the two retinæ. The interval attained was for the centre of the left eye '129 sec., and for the unexercised centre of the right eye '143 sec. At the peripheral spot in the left eye an interval of '1 sec. was required, and at the corresponding point in the other eye '210 sec. This exercise had notably lessened the interval at the points used in the left eye. It was interesting to ascertain whether it had had any influence on the points not exercised in this eye. It was found that the interval was similarly lessened for all peripheral points in the outer half of the field, but not for those in the inner half. Hence exercise of one excentric point seems to influence all points of the same half of the retina, and not those of the other half. More, this influence had extended to the corresponding half of the field of vision of the opposite eye, in which the interval was much shorter than in the non-corresponding half. This can only be explained by admitting the semi-decussation of the optic nerve fibres at the chiasma, and supposing that the exercise influences, not the retina, but the centre which receives the impressions from the corresponding half of each retina. M. Charpentier seems to have attended in his conclusions too exclusively to the sensory part of the process which he has measured, since a considerable part of the interval must have been occupied by the motor process involved in giving the signal. It is therefore clearly incorrect to speak of the interval as simply the "duration of perception." This consideration, however, brings out a new point of great interest. *A priori*, it might have been expected that exercise would have lessened the interval for the parts of the retina not practised, although in slighter degree, because the effect of exercise in abbreviating the interval must be supposed to tell upon the motor as well as the sensory portion of the process. But this seems not to be the case. The interval for the non-practised halves of the retina was not shortened, and hence exercise seems to facilitate chiefly the sensory portion of the process.

#### CITY DRINKING.

ONE of our contemporaries is informed by a medical man that "the growing habit with young men of taking nips of brandy," and glasses of "Irish," at all hours of the day, is becoming a serious evil. The practice of taking a glass whenever one meets a friend or acquaintance is, it is added, but too common, and in the City it often means half a dozen or more visits to the "shades" before luncheon. We hope our contemporary is wrongly informed. Certainly a more shady habit than that he describes could not be conceived. We are informed differently, and told that there is a marked tendency in the City for young men to take food, milk, or coffee, or sandwich, and not "nips"; further, that there is far more care in this matter in the City of London than in any other great city, as, for example, Liverpool, Manchester, or Newcastle, where casual and commercial drinking, as it may be called, is carried on with far less regard to consequences. Whether our information is right or that of our contemporary, it cannot be too plainly known that medical authorities are absolutely unanimous in the opinion that "nips" of spirit and odd glasses of wine and beer taken casually, without food, are an unmixed evil that every sensible man should discourage. There may be differences of opinion as to the amount of diluted alcohol at meals which is consistent with health and longevity, though even here there is a growing conviction that the quantity is a very moderate one. But alcohol in the empty stomach of a City man, with little fresh air or exercise to burn it off, is sheer harm, injuring the fine textures of the stomach and the neighbouring liver, and demoralising every function, from that of the brain to that of the kidney. No mixture of "bitters" makes this truth

any sweeter, or this habit less immoral. If teetotalers were less transcendental they might do immense good by forming a society the members of which should drink no alcohol but at meals. Meantime a word to the wise is enough; and no wise young man will continue a practice so unsanctioned by science and by religion.

#### THE LIFE GUARDS IN EGYPT.

THE correspondent of *The Times* with the army in Egypt has made a statement respecting the medical service of the Life Guards which appears to call for inquiry. He says that "it is unfortunate that, although an experienced surgeon-major like Dr. Spry has been provided to look after the health of these costly troops, he should have been left to his own unassisted skill to cure his patients, without the smallest supply of drugs, plaster, or other medical paraphernalia," on the passage from Alexandria to Aboukir in the *Calabria*. We are in a position to state that the *Calabria* was supplied with the usual medical and surgical equipment before leaving England, and there is no reason to suppose that it was removed from the ship on her arrival at Alexandria. If it was removed it would be desirable to know by whose orders, and what steps Surgeon-Major Spry took to have the necessary supplies put on board. Dr. Spry's experience has, we believe, been principally confined to service in London and at Windsor, and it is possible that he may miss those facilities for obtaining extra medicines, not included in the ordinary equipment, which he has enjoyed in these stations. But the equipment which has been found by experience to be sufficient for the general service ought to be enough also for "these costly troops." We have no doubt that Mr. Childers will cause a searching inquiry to be made into all the circumstances connected with the alleged deficiency with a view to ascertain to what extent it is true, and with whom the blame rests.

#### ELECTRICAL STIMULATION OF THE UTERUS.

THE influence of electricity on the uterus, whether empty or gravid, is a point on which authors have made various statements. This difference of opinion may be due to the circumstance that the conclusions have been drawn from the somewhat uncertain field of clinical observation. M. Dembo, in a note presented to the Académie des Sciences by M. Vulpian, has endeavoured to decide the question by experiments on animals. His observations at present relate only to the non-gravid condition. In the rabbit direct faradisation of the uterus or of one of its cornua causes a contraction at the point to which it is applied, and which extends for a distance of about twenty millimetres, but never reaches the other cornu. If one electrode is applied to each cornu, both can be made to contract in the neighbourhood of the poles, but not in the interval between them. Very different, however, is the effect when the application is made to the vagina. If both electrodes are applied to the vesical wall of the vagina, a manifest contraction is produced in both parts of the uterus, vermicular in character, passing from below upwards. If the application be made to the lateral portions of the vaginal wall, a contraction is produced only in the corresponding cornu. Local contractions on the corresponding side can be produced by placing the electrode on certain points in the broad ligament, but the contraction never extends to the whole uterus. It is impossible to produce contraction of the non-gravid uterus by faradisation applied through the abdominal wall. The excitability of the uterus of the rabbit was found to vary according to the age of the animal, and according to whether it had borne young or not. That of a young animal is so irritable that manifest contractions are excited by mere exposure to the air, but in old rabbits the uterus is much less susceptible. In some

dogs and cats no contraction of the empty uterus could be obtained by faradisation, in others slight contractions with distinct pallor were produced. Faradisation of the vaginal wall caused pallor of the mucous membrane, and also of the whole uterus, due apparently to contraction of the vessels, but no contraction of the substance of the uterus. Frankenhauser found that stimulation of the aortic plexus caused a manifest contraction of both cornua, and it is highly probable that an analogous nervous plexus is situated in the vesical wall of the vagina. The observations were made on animals under the influence of either chloral or curara.

#### THE ALEXANDER MEMORIAL PRIZE.

A MEETING of the Alexander Memorial Committee was held at the Army Medical Board on Saturday last to receive the report of the assessors appointed to examine the essays transmitted before the 31st December, 1881, in competition for the triennial prize. This consists of a gold medal and £50 in money, being part of the proceeds of the fund raised by subscription, chiefly among the officers of the department, as a tribute to the memory of Mr. Alexander, who died in 1859 while Director-General of the Army Medical Department. The prize is awarded triennially for the best essay on a subject selected by the committee of the fund, the competition being restricted to executive officers of the department on full pay. The selection is made from subjects included under military surgery, military medicine, and military hygiene alternately. On the present occasion the subject was "The Prevalence of Enteric Fever in the Army, its Etiology, Pathology, and Treatment, to be illustrated by the personal observation of the author." Seven essays were received in competition and referred to five assessors, selected by the committee, who reported as their unanimous opinion that the essay bearing the motto "*Palmam qui meruit ferat*" was entitled to the prize. On opening the accompanying note it was found that Surgeon-Major F. H. Welch, who has just returned to England from service in Madras, was the author of the essay. We have been requested to state that the other essays will be forwarded to any address the authors may desire if they will be good enough to communicate by letter, bearing as signature the motto of the essay, with the secretary of the committee, at 6, Whitehall-yard.

#### THE CURE OF HÆMORRHOIDS BY CARBOLIC ACID INJECTIONS.

AT a recent discussion at the New York Clinical Society on the Treatment of Hæmorrhoids, Dr. C. B. Kelsey referred to his experience with injections of carbolic acid. He uses a solution of one part of pure carbolic acid in six and a half parts each of water and glycerine, and of this he injects about five drops into each hæmorrhoidal tumour. For the operation no anæsthetic is required, and the subsequent pain is said to be very slight. In one case in which he used a solution of double strength each pile sloughed, and in another case, treated by one of his colleagues, Dr. Kelsey saw extensive ulceration caused, but this he attributes to want of skill in the manipulation. He has usually repeated the injections at an interval of about a week, so as to see the full effect of each injection before making another, and in this way the treatment may extend over months, but as it is painless and does not necessitate rest or even the abandonment of ordinary work, this is not a serious objection to the plan in many cases. This method of treatment, when carefully carried out, appears then to be safe, efficient, nearly, if not quite, painless, and not requiring rest or special nursing. It may be useful, therefore, where for any reason the ligature or clamp operation cannot be performed, and especially where it is important not to lay the patient up during treatment.

#### THE "EIRA" ARCTIC EXPEDITION.

BY the arrival of the search steamer, *Hope*, under Sir Allen Young, at Aberdeen, on Sunday last, all anxiety as to the safety of Mr. Leigh-Smith's expedition to the Arctic seas is set at rest. The whole party were found one day after the *Hope's* arrival at Matochhin Straits, Nova Zembla, on August 3rd, and have arrived, an unbroken company of twenty-five, in perfect health. The *Eira* left Peterhead on 14th June last year, and was abandoned on the 21st of the following August. The scientific results of the expedition are, therefore, likely to be of a meagre character, as the highest point reached was scarcely 80° N., and here, at Cape Flora, the vessel was nipped between the ice pack and the land floe, sinking two hours after, with the plants and fossils which had been collected, but not yet classified. This was on August 21st, and a hut was erected on the Cape, in which the whole party wintered, apparently with a well-provided larder, often added to by the skilful use of the gun. During the earlier winter the cold had not been severe, but in January, February, and March, it is stated to have been intense, sometimes as low as 80° of frost. On the 21st June of this year the whole party left Franz Josef Land in four boats, to make their way to Nova Zembla. After six weeks' heavy toil, including some hard work in dragging and rowing, they reached the Straits at the beginning of the present month, when they at once fell in with Sir Allen Young. Many of the points in Mr. W. H. Neale's medical report, published in another column, are important, but we must reserve the fuller consideration of them till next week.

#### SUDAMINA IN TYPHOID.

M. ALBERT ROBIN has examined the liquid of sudamina in a case of typhoid fever, in which the eruption was so abundant that the vesicles were confluent, and formed bullæ of considerable size, some of them being as much as a centimetre in diameter. More than three grammes of liquid were collected from them. It was transparent and colourless, but on standing, a deposit formed, consisting of whitish flocculi, and at the same time the liquid became opalescent. It had a slightly acid reaction, and a strong, unpleasant, odour. The microscope showed only a number of fine globules of fat and some epidermic cells. It contained neither albumen nor sugar, and was not rendered opaque by the addition of alcohol. No uric acid could be discovered in it by the murexide test. An analysis showed that it contained a considerable quantity of chlorides, but no trace of sulphates or phosphates: the proportion of water was 982, of solid matter 18, per 1000; the solids consisting of 14 parts of organic and 4 of inorganic substances. Hence the amount of organic material eliminated by the perspiration in typhoid must be regarded as considerable.

#### SMALL-POX AT WEDNESBURY.

SMALL-POX is somewhat widely prevalent at Wednesbury. According to a report by the medical officer of health two cases of the disease appeared in March last, and up to August 14th there had in all been 217 cases. Of this number 15 had died, 11 of the deaths having occurred in unvaccinated persons. On the whole the epidemic has hitherto been of a mild character, a circumstance which is locally regarded as a matter of gratification. In one sense this is right, but when we read of small-pox patients who, owing to the mildness of their attacks, cannot be induced to take to their beds, the dangerous aspect of the case also becomes apparent. These mild cases are a far greater source of danger to the public than severe cases would be, for the latter would necessarily be to some extent isolated in their own homes. As in so many other places, the provision of

proper means of isolation in Wednesbury has been delayed until it comes too late to prevent the epidemic, and it is only after five months of a small-pox prevalence that the decision has been arrived at to erect hospital tents or huts. The medical officer of health, speaking of an isolation hospital, has explained that in order that it may effect the intended object, it should “be ready beforehand to receive the early cases.” The same has often been said before, but the advice has been disregarded, and in a moment of panic temporary buildings are erected, which fail to comply with the needs of the districts for which they are provided.

#### TYPHOID FEVER IN PARIS.

THE last issued weekly return for Paris, relating to the seven days ending 16th inst., reports a marked increase in the mortality from typhoid fever in that city. The fatal cases of this disease, which had been 34, 31, and 47 in the three preceding weeks, rose to 106; this number included 69 of males and 37 of females. This marked disparity in the sex-proportion of the deceased typhoid fever patients in Paris has no parallel in London, and if constant in the former city should afford some clue to the true explanation of the continued fatality of the disease in the French capital. The figures in the Paris return under notice afford conclusive evidence of the suddenness of the present remarkable outbreak. It appears that on the 7th inst. 436 cases of typhoid fever were under treatment in the Paris hospitals, and that during the following seven days no fewer than 338 new cases were admitted; there were 98 cases discharged on recovery, and 39 deaths recorded during the week; so that 637 cases remained under treatment on the 13th instant, showing an increase of 201 during the week. Typhoid fever has been endemic in Paris in recent years, and in 1880 and 1881 the mortality from this disease was more than four times as great in that city as in London. During last week only 11 deaths from enteric or typhoid fever were registered in London, against the 106 in Paris. Judging from the French official returns, typhus fatality, however, is now unknown in Paris, although the disease is still far from extinct in London.

#### AN ACCIDENT OF LABOUR.

THE frequency with which the compression of the cranium, during the passage of the foetal head through a small pelvis, causes serious injury to the cerebral substance, is well known. It is not probable that the skilful use of forceps increases the amount of damage; it is possible, although difficult to prove, that thus the injury may sometimes be lessened, but whatever be the force or mechanism by which the foetal head passes through a narrow aperture, compression and damage there must be, in proportion to the contraction of the orifice. The fact of the injury to the cerebral tissue which results is strikingly illustrated by the discovery of Ruge that brain tissue may be found in the circulating blood in these cases, a fact which may also explain some other symptoms occasionally observed soon after birth in cases of difficult and instrumental labour. Ruge recorded three such cases, and a fourth has recently been placed on record by Dr. Paolo Negri of Milan. In his case, however, the foetal head was compressed in the uterus and not in the pelvis, the presentation being transverse. The woman was small of stature, only four feet six inches high, with old rickety deformities. Her first labour had to be terminated by embryotomy, in the second and third pregnancies labour was induced in the eighth month. In the fourth, she had gone to the full time and the arm presented. Several attempts at turning were made without success, the membranes having ruptured; ultimately version was effected under chloroform, but the child had been dead some

time. Its heart was carefully removed, the vessels having previously been tied. In the left auricle and left ventricle there was but little blood, but in the right auricle there was a quantity of liquid blood, mixed with numerous soft whitish fragments of tissue, similar in appearance to cerebral tissue. A drop of blood, mixed with a drop of a saline solution, showed under the microscope a considerable number of well-formed nerve cells, while minute capillaries were found in the whitish fragments.

#### “COUNTRY DOCTORS.”

OUR contemporary the *Globe* had recently a pleasant gossiping article on “Country Doctors,” wherein we find an attempt made to define the difference between country practice and town practice, the former being characterised as a “rough-and-ready” treatment of disease, while the latter is compared to the work of “the nineteenth century strategist,” who “has instruments and theories, inventions and methods, of which the other [the country practitioner] knows neither the use, nor often the existence.” “The city doctor,” we are told, “naturally devotes himself to the complications and the casuistries of disease. The country doctor brushes all these away, and fights with the few enemies he knows, and with whom he is accustomed to deal.” Of course it is recognised that this description applies only to the few country doctors of the “old type” now remaining. Railways and telegraphs and the periodical literature of the profession have almost improved the old type of practitioner off the face of the earth. In the broad lines of his reasoning our contemporary is right, and he argues the matter in a genial and appreciative spirit. Differences between the old way and the new do exist in medicine as in everything else; and it is well that, like old landmarks which are being removed in the course of modern improvements, these differences should be chronicled. By-and-by it will, probably, be found that in this, as in everything else, history repeats itself.

#### INDUCED PREDISPOSITION TO ANTHRAX.

THE temperature most favourable to the development of the bacteria of anthrax is that of the mammalia—i.e., a temperature of 37° or 38° C. Birds, and especially fowls, which have a higher temperature (about 42°) do not, under ordinary conditions, contract the disease. M. Pasteur, however, as is known, succeeded in communicating the disease to fowls, and in causing the bacteria to develop in their blood, by lowering the body-heat by means of the immersion of one foot for a considerable time in cold water. In the case of frogs, it was found by M. Gibier that at the ordinary temperature of water they are unaffected by a subcutaneous or intra-peritoneal injection of the liquids of anthrax, and it became important to ascertain whether, by raising their temperature to 37°, and thus rendering them for a time warm-blooded animals, the bacteria of anthrax would develop in their blood. Experiments directed to this end afford at least a partially affirmative answer. By compelling frogs to live in water at a temperature of from 35° to 37° C., M. Gibier succeeded in communicating the disease to them. The experiment does not always succeed, even when the conditions are the same. Of twenty animals, the disease was communicated to five only. The others died either as soon as they were immersed in warm water, or in the course of three or four days, without presenting evidence of infection. Two moreover resisted entirely. The blood of the other five, however, presented abundant bacteria, and these were also found in great numbers in the liver. A drop of blood taken from the heart of one and inoculated under the skin of a guinea-pig, killed it in forty-eight hours. The bacteria in the frog were remarkable for their length, which was far greater than that of the bacteria of the guinea-pigs. This

M. Gibier attributes to the slowness of the batrachian circulation, conjecturing that in the rapidly moving blood of the mammalia the rods may be broken. Some other points were also noted in the course of these experiments. It was observed that the frogs which proved susceptible had fasted for a longer or shorter time. Young, vigorous, newly captured frogs either resisted altogether, or died at the end of two or three days without any development of bacteria or increase in the size of the liver. Frogs which were suddenly removed from cold to hot water, without any gradual transition, as soon as possible after the inoculation, died more quickly from the disease than did those which had been acclimatised by degrees. Lastly, a curious fact was noted—that none of the frogs which had been previously inoculated in the cold water were infected by a previous inoculation in warm water. This may have been only an accidental coincidence, but it may possibly have been a vaccination phenomenon.

#### GENERAL HOSPITALS AND CASES OF INFECTIOUS DISEASE.

PENDING the provision of more perfect means for hastening the transmission of patients suffering from infectious disease, who present themselves at general hospitals, to the Metropolitan Asylums intended for such cases, house-surgeons and other authorities should take notice of the Article (4) of the Local Government Board's Order, wherein it is laid down that "if any person present himself at an asylum without the order and certificate required by Article 3, and the medical superintendent be satisfied that the person is suffering from fever or small-pox, and is in such a condition that a refusal to admit him without such order and certificate might be attended with dangerous results, the medical superintendent may admit such person, and the steward shall thereupon give notice in writing of such admission, accompanied by a written statement of the circumstances of the case, to the guardians of the union or parish in which the person last passed the night, if such union or parish be included in the metropolis, or if it be not included in the metropolis, then to the guardians of the union or parish in which the asylum is locally situated."

#### RUPTURE OF MEMBRANA TYMPANI, CAUSED BY DIVING.

DR. H. A. WILSON, of Philadelphia, has published in the *American Medical News* an account of two cases of rupture of the membrana tympani, caused by diving. In one case a man dived from a height of about twenty feet, and as he struck the water he heard a loud noise, which he likened to the firing of a cannon. Immediately afterwards he found that the hearing in his left ear was very imperfect, especially to high notes. A triangular rent in the lower anterior quadrant of the tympanic membrane was found. In the other case, a lad, in diving from a boat, heard something crack, and thought he must have struck the bottom; he then suffered from auditory vertigo, and complained of a whistling sound in his right ear when he blew his nose. A curved slit in the upper and posterior part of the membrane was seen through the otoscope. In each case Dr. Wilson carefully brought the torn edges into apposition, and fixed them by a thin layer of collodion painted on with a fine hair pencil. In each case bleeding had entirely ceased when the patient was seen, and there were no clots on the parts requiring removal. Dr. Wilson thinks that this accident may be more common than is generally supposed, and that some cases of deafness after diving, which are attributed to "water in the ear," are really the result of fissures in the drumhead. He explains the production of the injury by the sudden compression of the air in the auditory meatus

against a thin membrane insufficiently supported on the inner surface, and he accordingly suggests that, to prevent it, a full inspiration should be taken before diving, the mouth kept shut, and the soft palate raised to prevent escape of air through the nose. When a person has not sufficient control over the palate muscles to do this, holding the nose will serve the same purpose. The due compression of the air in the aural cavity is obtained by the contraction of the chest and the cheek muscles.

#### HEALTH MATTERS IN DUNDEE.

FROM action taken by the Police Commission at Dundee immediately after the death of Dr. Pirie, it was hoped that the sanitary supervision of that important town would be placed on a satisfactory footing. To state that during the past two months 700 cases of infectious disease have been reported to the authorities, that during July 67 cases ended fatally from the various zymotic diseases, that typhus fever is at present epidemic, and that by their recent local Act it is now compulsory upon medical men to report all infectious cases, is sufficient to indicate the importance and extent of the duties which must be performed by the medical officer. In the other three of the four largest Scotch towns, the medical officers of health are paid sufficient salaries to allow of their whole time being devoted to the duties of their office, and the result in each case has been most satisfactory both to the profession and the public. It is therefore disappointing to notice the action of the Dundee authorities, who are now advertising for candidates and offering £75 a year as a salary. This amounts to 10s. per thousand of the population; and this fact, as well as the feeble and antiquated arguments used to support the proposal, show that the recent liberal working of the Public Health Act, with all its beneficent results, is unknown or unappreciated by the authorities of Dundee. To the efficient management of sanitary matters in large towns nothing is more essential than the confidence and co-operation of the whole profession, and this is most likely to be obtained by the appointment of responsible men altogether independent of private practice. It is possible that a protest from the local Medical Association, backed by information easily available, might still be useful, as there is no reason to doubt that the authorities wish to serve the best interests of the town, if they did but know how.

#### THE HOURS OF LABOUR IN SHOPS.

A LEAGUE has been formed having for its object to reduce the hours of labour in shops. The patronage and support of distinguished persons have been secured. The movement has our warm sympathy on the score of health. It is injurious, to youths especially, to be kept standing in monotonous labour through many hours. At the same time we wish it were possible to devise some employment for the increasing leisure of the classes who do not naturally take great pleasure in reading, and who have few resources in themselves. A change from shop to music hall is not always a change for the better, though it may seem to provide relief.

#### THE PLAGUE AT PAKHOI, SOUTH CHINA.

MR. JOHN H. LOWNES, medical officer, Imperial Maritime Customs Service, Pakhoi, informs us that the outbreak of true bubonic plague which has been raging there since the end of March has almost entirely abated. The number of deaths during these last three months has been very great, the people dying on every side. The disease appears to have been confined to the natives. Medical treatment proved of little avail to check the scourge. The previous outbreak occurred in 1877.

## TWO PENETRATING WOUNDS.

THE *Indian Medical Gazette* of July 1st contains short accounts of two interesting cases. In one, which was under the care of Surgeon-Major R. de la Cour Corbett, a man thirty years of age, was struck by a Martini-Henry bullet, fired at a distance of 1950 yards. The ball entered on the right of and close to the fourth cervical vertebra, passed forwards, downwards, and to the left, and emerged between the second and third left costal cartilages. The man spat up about eight ounces of blood, but two hours later there was no blood in the sputum, although moist râles were heard over the upper part of the right lung. There was anæsthesia and analgesia of the right arm, which was cooler than the left, and bathed in clammy perspiration. No loss of motor power. The wounds were dressed with carbolic oil, two and a half per cent., and a mixture containing opium, ergot, and gallic acid was given. The wound healed without suppuration, and the man "was discharged well from hospital" ten days after the injury. The other case was that of a Hindoo child five years of age, under the care of Assistant-Surgeon Sasi Bhushan Kumar, who was gored by an ox five days before she came under treatment. An irregular wound was found about two inches below the left costal arch, through which about two feet of the omentum was protruding. The omentum, which was highly congested, was cut off beyond a ligature, and twelve days afterwards the child was discharged from the hospital perfectly cured. The previous treatment consisted in covering over the prolapsed omentum with a cloth moistened with mustard oil. The general treatment after excising the omentum consisted in "a few doses of calomel and soda" to move the bowels, and then "good food and tonics."

## DEATH IN THE CRICKET FIELD.

THE death of Mr. Carr, Captain of the Albemarle Cricket Club, after a very dashing and skilful innings on a very hot day, and just after receiving the plaudits of the spectators, excites many painful reflections—one of which is that if Mr. Carr had been content to forego cricket he would probably have been alive and well to-day. Another painful incident of the same sort has been reported since Mr. Carr's death. It is a pity that men who know they have weak spots will not preserve them; "lest," in the beautiful language of Scripture, "that which is lame be turned out of the way, but let it rather be healed." There are few perfectly sound men. Many who play the greatest rôles in the world are lives that no insurance office would take without an extra premium; but they contrive to go on by care as well as by strength. This category includes many with heart disease; for although the heart is liable to disease, it is also an organ capable of being rested, and which rewards its owner for consideration.

## LEGISLATION ON INFECTIOUS DISEASES IN GERMANY.

THE State authorities of Anhalt (Germany) have issued regulations enjoining the placing, as far as possible, in isolated rooms, of the bodies of persons who have died from cholera, small-pox, typhus, diphtheria, dysentery, scarlet fever, or measles. In the interval between death and interment, the necessary measures for disinfection have to be observed. No exhibition of such bodies is allowed; and the mourners and other persons attending the funeral are not permitted to assemble at the house where the death has taken place. Contraventions of these regulations make the offenders liable to a fine of thirty shillings, or to imprisonment.

## FEVER NURSES AND THE FEVER HOSPITAL.

THE Committee of Management of the London Fever Hospital announce that they have made arrangements to supply trained nurses to nurse at home any person suffering from infectious fever other than small-pox. The regulations seem to be satisfactory, excepting perhaps that concerning the fees. A fee of three guineas a week seems to be unnecessarily large. One of the regulations is to be specially noted, and runs as follows:—"With a view to preventing the infection of others, the nurse will be provided with a uniform which she will wear while in attendance on the patient. She will also have a second change of clothes for use out of doors, which on no account are to be taken into the sick room." There is no reason why both nurses and medical men in infected rooms should not wear a surplice of some kind—an ordinary night-dress does very well,—which can be doffed and put into a box provided for the purpose when leaving the room. The precautions taken against the conveyance of infection should be in excess of what is necessary. It is still painful to see even nurses of infectious cases comparatively insensible to the risks to be avoided.

## CHARGING FOR CERTIFICATES OF DEATH.

A JURY at Bethnal Green at an inquest on a child, two years and a half old, found that deceased died from sunstroke, but that the doctor's conduct was deserving of censure. The doctor had seen the child twice, once at his own surgery and again at home. When applied to for a certificate of death he was alleged to have demanded a payment of 2s., and on that not being forthcoming he said he would bring the case before the coroner, as the death was doubtful. The medical man strongly denied that he refused the certificate on that ground. One of the witnesses said she quite understood this money was demanded not for the certificate, but because the money due to the doctor was withheld. We cannot but think that the doctor's conduct in this case has been misunderstood; if so, an injustice has been done by the remarks of the coroner and the finding of the jury. Of course, a medical man has no right to make the giving of a certificate of death depend on his being paid for his attendance.

## DRUG FARMS.

DR. ATTFIELD'S address at Southampton on Tuesday contained a suggestion which we trust may bear fruit. He is of opinion that much good might be done by the establishment in this country of drug farms, where our chief medicinal plants might be systematically cultivated and collected. For the majority of vegetable drugs we have still to rely on the somewhat capricious kindness of unaided nature, and as regards quantity and quality, we are to a very great extent in the hands of ignorant and irresponsible collectors. Why should not drug farms be more generally established in Great Britain? Many food farms are being thrown out of cultivation, and there is no difficulty in procuring land. Would not farming other than food farming be likely to prove remunerative? Flower farming and fruit farming are among the most lucrative callings in this country.

## COMPULSORY VACCINATION IN SWITZERLAND.

AN intelligent writer in *The Times* writes from Lausanne to caution anti-vaccinationists against misconstruing the recent popular vote in Switzerland on the proposed law on epidemics. The vote is to be regarded as one against centralisation, and not against compulsory vaccination, which, the writer avers, will be equally compulsory under a cantonal law. The poor anti-vaccinationists get little comfort.

## TYPHUS PROSPECTS.

THE appearance of typhus as a cause of mortality in our large towns is a matter calling for the serious attention of sanitary authorities. It is now more than ten years since this disease was epidemic, and although much has been done during the interval in the removal of filthy and overcrowded tenements, yet we are painfully convinced that many appropriate typhus haunts remain in various parts of the kingdom, and that they can only slowly be got rid of. In the meantime we hear of this disease at Liverpool, at Manchester, at Gateshead, at Maryport, at Sunderland, and other places, and there is every reason to fear that as the winter advances many sanitary authorities may find themselves confronted with this fatal and infectious form of fever. Of all the specific fevers typhus is perhaps the one which most loudly calls for efficient measures of isolation. Associated as it is with that peculiar form of filth which is found in connexion with destitution and overcrowding, nearly all who are attacked by it need for their own sakes, and for the protection of the public, to be immediately removed from their homes to proper isolation hospitals. When an epidemic attacks a town, it too often transpires that the question of making provision for the isolation of infectious diseases has for some time been under consideration, but the intention has never been carried out, and the spread of infection cannot then be stayed by the isolation of the first patients attacked. The prospects of typhus, as the colder months advance, should, especially in our large and crowded centres of population, lead to immediate and decisive action in this matter of hospital provision.

## LONDON BAKEHOUSES.

ATTENTION has recently been directed to the condition of the London bakehouses, and not, as it would seem, without cause. The investigations set on foot in certain districts have led to the discovery of a very insanitary state of affairs. Bakehouses are almost invariably underground, and it is found that, in common with the majority of basements, they are more or less defiled by the impurities of the surrounding soil. The heat doubtless draws the foul gases and the moisture to the locality. Nor are the bakeries in London always conducted with due care and cleanliness. For example, one officer of health reports that he found an instance in which "a man suffering from fever had been sleeping for some nights on the flour sacks belonging to the bakehouse." This suggests disquieting thoughts. It is well that, every now and again, the old and, as it may be supposed, reformed, abuses of trade and social life should be subjected to renewed inquiry.

## SMALL-POX IN CAPE TOWN.

THE *Port Elizabeth Telegraph* properly devotes much of its space to information about small-pox in Cape Town, and the alarm occasioned by it. At a meeting of the Town Council, one councillor seemed to expect very beneficial influence from heavy showers of rain. We caution all authorities and all individuals against trusting in anything but vaccination of the children and revaccination of all who are not children. Isolation of the sick as soon as the disease is declared is very good; but the healthy can protect themselves only by vaccination, and by revaccination after childhood is over.

DR. R. W. BURNET, of Wimpole-street, left Liverpool on Thursday by the *City of Rome*, to join the party of Her Royal Highness the Princess Louise (the Marchioness of Lorne), in medical attendance, during their approaching tour. Dr. Burnet will reach the Falls of Niagara on Sept. 4th.

DRS. MORTON and DANA publish in the *New York Medical Record* (July 29th) a report of the Microscopical Appearance of Guiteau's Brain. They made numerous sections from various parts, and used several kinds of staining reagents. The most constant appearance consisted in the presence of rounded translucent bodies,  $\frac{1}{16}$  in. to  $\frac{1}{8}$  in. in diameter, which gave the aniline blue, but not the iodine, reaction of amyloid matter. They were not soluble in ether, nor stained by osmic acid, and were insoluble in acetic acid. The writers regarded them as post-mortem products, in spite of the aniline reaction. The cortex contained a few thickened bloodvessels, but no other changes were noted.

IN a paper on the Etiology of the Simple Round Ulcer of the Duodenum, Dr. Hiava, assistant in pathological anatomy at Prague, concludes that there are two kinds of ulcers, the acute and chronic. Acute ulcers are produced by an inflammatory or mycotic process, and often lead to perforation; but they frequently cicatrize or are converted into a chronic ulcer. An acute ulcer is sometimes formed from embolism. Chronic ulcers, firstly, may arise in an inflammatory process and be developed from acute; secondly, they may ensue upon local venous stasis; thirdly, they may be mechanically produced by injury of the mucous membrane (hæmorrhagic erosion), and perhaps through the action of the gastric juice.

FROM a study of several cases in an epidemic of measles in the Children's Asylum of the Philadelphia Hospital, Dr. John Keating (*Boston Medical and Surgical Journal*) declares that the presence of micrococci in the blood is very significant of the malignant type of the disease; that the micrococci may invade the corpuscles, both red and white, and thereby add another danger to life; and that the remedies indicated by their presence are alcohol, the vegetable acids, and bichloride of mercury. Acting upon the principle that alcohol checks the development of micrococci in culture-solutions, he avers to have saved some cases by the free administration of whisky.

THE address of Dr. Siemens, President of the British Association, at Southampton on Wednesday, dealt mainly with the subject with which his name is prominently associated. Whilst the great advantages of electric lighting were set forth, the merits of gas, both for illuminating and heating purposes, were fully acknowledged. The discourse illustrated conspicuously the benefits resulting from the union of science and practice, and was received with marked favour by the audience.

DR. HENRY MAC CORMAC has published a timely protest, penned with much vivacity and ingenuity, upon the Etiology of Tubercle, with comments on Dr. Robert Koch's Bacilli. The pamphlet is dedicated to Dr. Wilson Fox, and its aim is to show that the bacilli are themselves of secondary importance as compared with the real tubercle-generator—"rebreathed air."

THE Local Government Board inquiry into the alleged deaths from vaccination at Norwich was opened by Mr. J. J. Henley and Dr. Airey on Wednesday, continued on the following day, and was not concluded at the time of our going to press. We postpone consideration of the matter until the inquiry shall have terminated, and the whole of the facts have been brought out.

IT is stated that a vessel with two cases of Asiatic cholera on board has arrived at Foynes in the Shannon. The vessel has been placed in quarantine.

MR. THOMAS HOLMES, the vaccination officer of the Leeds Union, reports that out of 2793 births registered in the second half of 1881, only 1.1 per cent. still remain unaccounted for as regards vaccination. Mr. Holmes is a painstaking officer, and, setting aside a few members of the board of guardians who appear to have anti-vaccination sympathies, his labours are appreciated by those whom he serves.

THE officers of the Army Medical Department at Netley have issued invitations to a garden party to the members of the British Association attending the annual meeting now being held at Southampton.

"THE Medical History of Worcestershire" is the title of a pamphlet written by Mr. A. H. F. Cameron—no doubt in view of the late meeting of the British Medical Association. It is chiefly of local interest, for the author contents himself with very brief biographical sketches of the leading Worcester doctors of past days.

SMALL-POX is prevalent at Gateshead. Most of the persons attacked have been removed to a hospital for infectious disease, and the sanitary authorities are adopting measures to check the spread of the epidemic.

THE officers of the Army Medical Department have erected a handsome white marble cross in the cemetery at Lahore over the grave of the late Surgeon-Major Robert Murphy, who died at Fort Lahore on September 1st last year.

SURGEON-MAJOR SANDFORD MOORE has been appointed to succeed Surgeon-Major Notter as Assistant-Professor of Hygiene at the Royal Victoria Hospital, Netley.

## Pharmacology and Therapeutics.

### IODOFORM IN LUNG DISEASE.

PROFESSOR SEMMOLA of Naples has published an account of the treatment of caseous broncho-pneumonia by iodoform, and has added to it an urgent entreaty to practitioners in all countries to repeat his experiments, as he believes this to be one of the most important uses to which iodoform can be applied. During the last three years he has treated many cases in this manner, not only of broncho-pneumonia, but of bronchial catarrh, asthma, &c. Expectoration lessens, often very rapidly, and with it the cough and paroxysms of dyspnoea, perhaps partly in consequence of the local anæsthetic action of the drug. The secretion in the bronchial tubes, and in small cavities, is, he believes, disinfected. Pyrexia gradually lessens, and he thinks that the fall in the temperature is to be ascribed to this disinfection of the secretion and putrid material, which is being constantly absorbed from foci of softening. The local process seems to be favourably influenced, and in some cases a condition very near the normal seems to be regained, of course only in cases of broncho-pneumonia in the first stage. The dose employed varied between five and fifty centigrammes daily, according to the varying tolerance of the digestive and nervous system. It is best borne made up into pills, with extract of gentian or some other extract. Small doses answer best, which can be repeated as frequently as every one or two hours. Inhalations may also be employed, the iodoform being dissolved in turpentine, and this inhaled three or four times a day. Semmola disclaims any intention of bringing forward iodoform as a remedy for tuberculosis or all caseating affections of the lungs. Several cases, supposed to be tubercular, have, however, been recently published in which remarkable results have been said to follow

the administration of iodoform. Mook gave it in doses of one centigramme, and observed the signs of cavities gradually to disappear. Baeler observed what were believed to be the symptoms of tubercular meningitis to disappear under its use. In neither of these cases, however, does the diagnosis of tubercle appear to rest on any strong grounds.

### THE ACTION OF QUININE AND SALICYLIC ACID ON THE EAR.

In order to ascertain whether the noises in the ears produced by salicylic acid and by quinine are due to a congestion of the labyrinth, Dr. Kirchner has instituted some experiments in the pharmacological laboratory at Würzburg. The noise in the ears is sometimes accompanied by giddiness and deafness, which, usually ceasing when the medicine is discontinued, sometimes persists as a serious malady. Kirchner employed in his experiments rabbits, cats, dogs, and guinea-pigs. His conclusions are that both these agents cause hyperæmia of the tympanum, which may go on to hæmorrhage, and that the whole of the labyrinth participates in the congestion. It may become so intense that, if it lasts long, it will cause of necessity an alteration in the nerve filaments, and it may lead to exudation. This congestion he regards as produced by a vaso-motor mechanism. In this conclusion, however, another series of observations made by Weber-Liel and Guder does not agree. They observed carefully the symptoms produced in certain healthy individuals by a moderate dose (fifteen grains) of quinine, and noted, during two hours and a half, a gradual fall in the temperature of the external auditory meatus, corresponding to the diminution in the general temperature of the body. No hyperæmia could be detected in the meatus, the membrana tympani, or the handle of the malleus, either during this period or later. On the contrary, in five cases a slight hyperæmia which existed previously was found to disappear. The subjective noises in the ears came on at the end of an hour or an hour and a half, and continue for ten or twelve hours, while the deafness comes on one or two hours later than the tinnitus, and is greatest at the time that the general temperature of the body is lowest. Similar experiments were made with salicylic acid. Four or five grammes of salicylic acid caused a diminution in the temperature of the external auditory meatus, which falls in the course of two or three hours to 95°. No indication of congestion could be discovered, and, as in the case of quinine, previous hyperæmia became lessened. Noises in the ear came on later and lasted longer than in the case of quinine. The deafness is very marked, and continued in some instances for several days, and in some cases, in which there existed previous ear disease, the loss of hearing was more prolonged, enduring in one case for nine months. In more than half the cases giddiness came on a little after the subjective symptoms. Comparing the effects of salicylic acid and quinine, it appears that the former causes a less considerable depression of temperature and a more prolonged diminution in hearing. It is difficult, therefore, to ascribe the aural effects either to congestion or to anæmia, and if these observations are reliable, it would seem to be due to a primary nervous influence.

### SALICYLIC AND CARBOLIC ACIDS.

The comparative value of salicylic and carbolic acids given internally was the subject of a recent paper by M. Desplats of Lille. Each has an analogous action as a febrifuge, and the well-known effect of salicylate of soda in acute rheumatism can be produced, in some cases at least, by carbolic acid, and the rectal administration of either may be substituted for that by the mouth when there are difficulties in giving it by the latter. Urinary disturbances are unimportant and quickly cease if the dose is lessened. Albuminuria is rare, and passes off if the drug is omitted for a short time. M. Desplats mentions, for instance, a case of phthisis, in which, on account of high fever, two injections were given daily for two months, each containing half a gramme of carbolic acid, without any ill effect. In the discussion which followed at the Académie de Médecine, M. Dujardin-Beaumez expressed the opinion that the free use of carbolic acid in injections entailed a considerable risk of pulmonary congestion, and the opinion was corroborated by several other speakers.

### PEROXIDE OF HYDROGEN IN SURGERY.

The powerful germicidal properties of peroxide of hydrogen, the *eau oxygénée* of the French, have led MM. Péan and Baldy to test its practical value as a surgical dressing for

extensive wounds and ulcerations of various nature, as an injection into sinuses and cavities, such as the bladder, the nasal cavities, and also in the form of spray as a substitute for the carbolic acid spray in major operations, such as ovariectomy. It was applied by means of compresses covered with an impermeable material, to prevent evaporation. During the dressings a spray of it was employed. The preparation used was absolutely neutral in reaction, and contained four or six times its volume of oxygen; but for the injection of sinuses or closed cavities a weaker solution was employed, containing only one or two times its volume of oxygen. The results obtained from more than a hundred cases have been most satisfactory, in grave as well as in trifling cases. Under the treatment recent wounds made with the bistoury or thermo-cautery, old wounds even when covered with gangrenous tissue, complicated with lymphangitis, or erysipelas, rapidly assumed a healthy aspect, granulating freely with perfectly sweet creamy pus. Chronic ulcerations rapidly cicatrised, and amputation wounds presented a strong tendency to heal by first intention. The general condition of the patients presented at the same time a marked improvement. The results are stated to have been quite as satisfactory as those obtained with carbolic acid. It has the additional advantage of being free from any toxic property, from any unpleasant odour, and of causing no pain. The results were especially satisfactory in some cases of varicose ulceration of the legs, intra-articular abscesses, ozæna, and purulent cystitis. In some remarks on the occasion of M. Péan's communication to the Académie des Sciences, M. Paul Bert, to whose investigations the French are indebted for most of their knowledge of the subject, pointed out that in the surgical use of this substance its influence was exerted in two ways, first by killing the organisms, and secondly by continually liberating oxygen on the surface of the wound. He insisted on the care which must be taken to secure its purity, since most commercial specimens contain a considerable quantity of sulphuric acid.

#### SALICYLATED STARCH.

Kersch has recommended salicylated starch in the treatment of eczema. It is prepared by mixing starch gradually with salicylated alcohol of a strength of 2 per cent., allowing the starch to sink to the bottom, pouring off the supernatant liquid, squeezing the starch in muslin, and drying it at a temperature of 80° C. In treating eczema it is recommended that after the scales have been removed the patches should be dried with antiseptic cotton-wool, then moistened with a 2 per cent. solution of salicylic acid in alcohol, and afterwards covered with a thick layer of salicylated starch.

#### CONVALLARIA MAJALIS.

An old remedy in Russia for dropsy, the convallaria majalis, has been recently tried in France in the form of (1) an aqueous extract of the leaves, which appears to be a feeble preparation; (2) an extract of the flowers which has a more powerful action on animals than on man; and (3) an extract of the whole plant. M. Hardy, however, has obtained an alkaloid, convallarine, in an amorphous form, which seems to possess a potency comparable to that of digitaline. The dose of the extracts which has been employed is from one to two grammes of the extract of the flowers or the entire plant. In the tortoise a remarkable retardation of the heart is produced; its frequency falls in the course of a minute from 36 to 4. A very marked retardation of the pulse and respiration was caused in the dog by a subcutaneous injection of five centigrammes of the extract. M. Germain Sée has tried it in twenty cases of disease. In three it had no effect, but in the others its influence was remarkable. It has a powerful diuretic action, increasing the amount of urine to about three times its previous volume. The cases treated were three of mitral regurgitation, two of dilatation of the heart, simple hypertrophy, aortic regurgitation, simple anæmia, chronic pericarditis, and diabetes. Russian physicians believed that the agent was chiefly useful in nervous affections of the heart; but this is, in the opinion of M. Sée, an error. It has no action on the digestive organs, and is perfectly well borne. It rather increases than lessens the appetite, and facilitates the action of the bowels. The diminution in the heart's frequency, under normal conditions, amounts to 10 or 15 beats per minute. Irregularity, especially of nervous origin, is lessened. Sensations of pulsation in distal vessels—e.g., in the head—are removed by it. At the same time the force of the cardiac action is increased.

## Public Health and Poor Law.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF INSPECTORS TO THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

*Hull.*—Dr. Airy has prepared for the Local Government Board a very exhaustive report on the sanitary condition of the borough of Hull, the more immediate object of his inspection having been the serious mortality which has prevailed there from scarlet fever. A very complete general description of the borough is given, special prominence being accorded to its topographical features. The town lies on an alluvial flat, waterlogged to within a few feet of the surface; it is in many parts densely packed and overcrowded, and the sewage is dammed back in the outfall sewer for over seventeen out of every twenty-four hours. Considerable efforts are made to mitigate these local disadvantages. A dry system of excrement removal is in vogue, which appears, however, to require more careful scavenging, general refuse is regularly collected and then destroyed in one of Messrs. Bailey and Fryer's destructors, and the flushing of the sewers is effectually performed. The administration is, however, in several respects seriously lax. Notwithstanding the risk of the importation of infectious disease by water into this important seaport town, which has received in one year as many as 70,000 emigrants, there is no check upon vessels entering the town and no security whatever against the introduction of infection. With a population of 154,250, the medical officer of health is paid a sum which can only command a very small amount of his time, and which is wholly inadequate to the services required; and the fact that he is not independent of private practice is evidently a great hindrance to his receiving that co-operation from his colleagues which such an officer for a district like Hull must constantly stand in need of. The general death-rate for the borough is about 24.0 per 1000 of the inhabitants, and it is satisfactory to note that improvement in this respect has for some years been in progress, a fact which should encourage the authority to persevere in their efforts to remove the many sanitary defects still to be dealt with. But in 1881 the mortality was swelled to an alarming extent by deaths from scarlet fever. This disease, never wholly absent from the borough, slowly increased during the first half of the year. In July, however, a rapid extension took place. The infectious hospital, which then only contained twenty-one beds, was put in requisition, and, as it filled, two new wards were hurriedly erected. But, as Dr. Airy says, the disease was then beyond control, and it had to burn itself out. From the beginning of September up to the end of the year the fatal cases varied from 19 to 40 a week, and as many as 680 deaths from this one cause alone were registered for 1881, a total of 417 being recorded in the last quarter of the year. During the first three months of the present year some signs of abatement were observed, the fatal cases, however, numbered as many as 140. According to the Registrar-General's return for the second quarter a reduction to 63 scarlet fever deaths had taken place. But the disease, unfortunately, also spread to adjoining districts, and some report as to these is also given by Dr. Airy. Nothing short of a very perfect system of notification of infectious diseases, together with ample provision for the isolation of first attacks, can be expected to prevent epidemics of scarlet fever in our large towns. It is true that much may be done to stay their progress and to limit their extent by an energetic sanitary administration, yet so long as the disease is regarded with such apathy by a large proportion of the poor and ignorant who are often crowded together, and who do not deem it necessary to seek medical advice even when this can be gratuitously procured, any thought of its eradication must for the time be given up. Education must go hand in hand with an intelligent sanitary administration before any such result can be attained.

#### REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Huddersfield (Urban).*—Dr. Cameron's quarterly return for Huddersfield, relating to the three months ending June last, afforded fairly satisfactory evidence of the sanitary condition of that borough during the period under review. The

population of the borough is estimated at 83,271, or a few hundred less than the Registrar-General's estimate. The birth-rate and death-rate of the borough during the quarter are calculated at 29.5 and 20.8 per 1000 respectively. Huddersfield is one of those towns in which the notification of certain infectious diseases is compulsory; and Dr. Cameron, while he refers to the freedom of the town from the fatality of those diseases which are scheduled for notification, also calls attention to the considerable mortality caused during the quarter by measles and whooping-cough, of which notification is not required. It appears, however, from the Registrar General's quarterly return that, during the second quarter of this year, the fatality both of measles and whooping-cough in Huddersfield was below the average rate from those diseases that prevailed in the twenty-eight large towns dealt with in that return. Since the end of June, however, measles fatality has assumed exceptional proportions in Huddersfield, and twenty-nine more deaths from this cause were registered during the six weeks ending the 12th inst. The general ignorance that prevails among the lower classes of the dangers to be feared from neglected measles, renders it most desirable that this disease should not be omitted from the scheduled list for notification. The value of Dr. Cameron's excellent quarterly return would be enhanced by the addition to his first table of the borough statistics for a few preceding quarters. The headings of the columns showing infant mortality should, moreover, be more precise. We presume that the column headed "under five years" includes only the deaths of children aged four years and under five. We should, indeed, prefer to see a different classification of the ages of decedents, as it appears scarcely necessary to devote five columns to deaths of children under five years. The borough infectious diseases hospital was comparatively empty during the quarter, but twenty cases of admission were reported.

*East Cowick.*—An interesting report has been prepared by Dr. J. Mitchell Wilson on an epidemic of enteric fever in the little village of East Cowick in the Goole rural and sanitary district. The starting-point of the disease appears to have been an unrecognised attack of enteric fever, which led to the contamination of a public well by reason of soakage from a leaky drain belonging to the cottage where the case occurred. The well is a shallow one, standing midway between the cottage in question and a sewer ditch, and surface-drainage was found to make its way into it on all sides. Of the families using this water 72 per cent. were attacked with distinct enteric fever, and, including certain doubtful attacks, 85 per cent. were found to have suffered; whereas out of twenty-four families having a different supply, only three, or 12 per cent., suffered, and this notwithstanding the fact that numerous sources of infection existed by reason of the specifically contaminated privies and drains. Confirmatory evidence as to the pollution of the public well was afforded by chemical analysis of its contents, and it is satisfactory to note that amongst the remedial measures which have been carried out under Dr. Wilson's advice, is the provision of an ample water-supply which is in every way fitted for all household purposes. The report is well drawn up, and it is evidently based on a very careful and exhaustive inquiry.

#### MODEL BY-LAWS OF THE LOCAL GOVERNMENT BOARD.

With the issue of the 15th and 16th Series the code of model by-laws is completed. These last two series relate to mortuaries and the regulation of offensive trades.

*Mortuaries.*—The series relating to mortuaries is in itself very brief, containing as it does only six clauses dealing with the removal of bodies of persons who have died either of infectious or non-infectious diseases, with the decent behaviour of persons engaged in any duties in the mortuary, and with the penalties for offences against the by-laws. But the series, as issued by the Local Government Board, contains in addition a lengthened explanation of the application of the several sections of the Public Health Act with reference to mortuaries; a statement of the circumstances as to site and structure which should be held in view in the construction of such buildings; advice as to the administrative arrangements which are desirable; and, lastly, a plan of mortuary premises for a town of 10,000 inhabitants, embodying the principles laid down by the Board. The plan provides two main buildings, one being the caretaker's residence, the other the mortuary itself. In the latter is an apartment where the clothes of persons found dead can be seen by relatives or others who do not wish, except in case

of necessity, to see the dead bodies. One or more of the bodies can be fully viewed through a glass screen, fitted with blinds, an arrangement by which visitors and others need not enter the mortuary chamber itself or come in contact with infection. We note the absence of any post-mortem room on the mortuary premises. The reason of this is, doubtless, because, under section 143 of the Public Health Act, 1875, the power of local authorities to provide and maintain places where post-mortem examinations may be carried out is conditional on such places being elsewhere than at either a workhouse or a mortuary.

*Offensive Trades.*—This series contains a separate code of by-laws with respect to thirteen different trades—namely, the trade of a blood-boiler, of a blood-drier, of a bone-boiler, of a fell-monger, of a tanner, of a leather-dresser, of a soap-boiler, of a tallow-melter, of a fat-melter or fat-extractor, of a tripe-boiler, of a glue maker, of a size maker, and of a gut-scraper. A preliminary memorandum explains how far the provisions of the Public Health Act affect offensive trades, and it quotes a series of judicial decisions with regard to what does in reality constitute an offensive trade. From the cases cited it seems evident that no trade can be regarded as an offensive one within the meaning of the Act unless it be *ejusdem generis* with the six trades specified in section 112, and that in seeking to establish an analogy between any trade and those specified much importance will attach to the identity or similarity of the materials used in the process. The sanitary authority should also in all cases be prepared with evidence to show that the trade processes in question are as a matter of fact of a noxious character. With a view of aiding local authorities in their efforts to deal with such trades, Dr. Ballard's report on Effluvia Nuisances has been reprinted, and it can now be procured by all who are interested in the subject.

On consideration of the report of their inspector, Mr. Thornhill Harrison, the Local Government Board have resolved to form the Barking Town ward into a Local Government district under the provisions of the Public Health Act. Barking, therefore, will shortly be called upon to form a local board, and will be dis severed from the government of the Romford Rural Sanitary Authority.

Mr. De Pape, surveyor to the Tottenham Local Board, has published a letter in which he denies that the poisoning of fish in the river Lea had resulted from a discharge from the sewage works in the northern suburb.

#### VITAL STATISTICS.

##### HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns, 5779 births and 3800 deaths were registered in the week ending the 19th inst. The annual death-rate in these towns, which had slowly increased in the four preceding weeks from 19.0 to 21.2, further rose last week to 23.4. The lowest rates in these towns last week were 16.3 in Birkenhead, 17.0 in Wolverhampton, 17.1 in Brighton, and 17.5 in Derby. The rates in the other towns ranged upwards to 30.4 in Leeds, 30.6 in Salford, 30.7 in Sunderland, and 33.4 in Nottingham. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 930, showing a further increase of 238 upon recent weekly numbers; 660 resulted from diarrhoea, 89 from whooping-cough, 84 from scarlet fever, 69 from measles, 47 from "fever," 30 from diphtheria, and 11 from small-pox. The lowest death-rate from these diseases occurred last week in Derby and Birkenhead, and the highest in Preston, Hull, and Nottingham. Diarrhoea fatality showed a further general increase last week, and was most excessive in Leicester, Preston, Cardiff, and Nottingham. Whooping-cough caused the highest death-rates in Sunderland and Blackburn; scarlet fever in Portsmouth and Hull, measles in Huddersfield; and "fever" in Liverpool, Preston, and Portsmouth. Small-pox caused five deaths in London, three in Birmingham, and one each in Wolverhampton, Nottingham, and Newcastle-upon-Tyne. The number of small-pox patients in the metropolitan asylum hospitals, which in the sixteen preceding weeks had declined from 350 to 123, further fell to 111 on Saturday last; 18 new cases of small-pox were admitted to these hospitals during last week, against 16 and 19 in the two preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had increased in the

four preceding weeks from 157 to 223, declined again last week to 197. The causes of 129, or 3·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Plymouth, Nottingham, Birkenhead, and Cardiff; whereas the proportions of uncertified deaths were largest in Wolverhampton, Liverpool, Halifax, and Sunderland.

#### HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had been 21·3 and 20·1 per 1000 in the two preceding weeks, was 20·7 in the week ending the 19th inst.; it was 2·7 below the mean rate last week in the twenty-eight large English towns. The deaths referred to the principal zymotic diseases in these Scotch towns were 131 last week, and showed a further increase upon recent weekly numbers; they included 62 from diarrhoea, 17 from diphtheria, 15 from "fever," 15 from whooping-cough, 14 from scarlet fever, 8 from measles, and not one from small-pox. The death-rate from these principal zymotic diseases averaged 5·6 per 1000, and was 0·5 below the mean rate from the same diseases in the large English towns. The 62 deaths attributed to diarrhoea showed a further slight increase upon recent weekly numbers, and were 23 above the number in the corresponding week of last year; the fatality of this disease was higher last week in the English than in the Scotch towns. Diarrhoea was most fatal last week in Glasgow, Edinburgh, and Paisley. The 17 deaths from diphtheria showed a further increase upon the numbers in recent weeks, and included 9 in Glasgow and 2 each in Edinburgh, Aberdeen, and Greenock; Dr. Littlejohn, however, reports but 1 in Edinburgh. The deaths referred to "fever," which had been 10 and 8 in the two previous weeks, rose to 15 last week, and included 7 in Glasgow, 3 in Dundee, and 2 both in Edinburgh and Perth; Dr. Littlejohn, however, reports but 1 in Edinburgh. Twelve of the 15 fatal cases of whooping-cough, and 8 of the 14 of scarlet fever, were returned in Glasgow. Scarlet fever caused 3 deaths in Edinburgh and 2 in Paisley. The 8 deaths from measles showed a decline from the numbers in recent weeks, and included 3 in Leith and 2 in Dundee. The deaths referred to acute diseases of the lungs in the eight towns, which had steadily declined from 95 to 71 in the five preceding weeks, were 73 last week, and 4 below those attributed to the same diseases in the corresponding week of last year.

#### HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 20·8, 22·9, and 23·5 in the three preceding weeks declined again to 20·1 in the week ending the 19th inst. During the first seven weeks of the current quarter the death-rate in the city has averaged 20·9 per 1000, against 18·6 in London and 18·1 in Edinburgh. The 134 deaths in Dublin last week showed a decline of 23 from the number in the previous week; they included 10 which were referred to diarrhoea, 2 to "fever," 2 to diphtheria, 1 to whooping-cough, and not one either from small-pox, measles, or scarlet fever. Thus 15 deaths resulted from these principal zymotic diseases, against 16 and 15 in the two previous weeks; these were equal to an annual rate of 2·2 per 1000, against 4·4 in London and 4·3 in Edinburgh. The fatal cases of diarrhoea, which had been 5, 6, and 9 in the three preceding weeks, further rose to 10 last week, and exceeded the number returned in any previous week of the year. The two deaths referred to "fever" (enteric, typhus, or simple), declined to 2 last week, from 7 and 6 in the two previous weeks. The 2 fatal cases of diphtheria exceeded the number returned in any week since the middle of May. The deaths both of infants and of elderly persons showed a considerable decline from recent weekly numbers. The causes of 19, or more than 14 per cent., of the deaths registered during the week were uncertified.

**SANITARY INSTITUTE OF GREAT BRITAIN.**—At the autumn Congress for 1882, to be held at Newcastle-upon-Tyne from the 26th to the 30th of September, the collection of sanitary apparatus and appliances in connexion with the Congress will be exhibited in the Tyne Brewery Buildings, Bath-lane, from September 26th to October 21st. The lectures and general meetings will be held in the Town Hall; the sectional meetings in the lecture room, Nelson-street.

## THE SERVICES.

### THE EXAMINATION FOR THE PUBLIC SERVICES.

The competitive examination for commissions in the Medical Service of the Army, Navy, and India commenced on Monday last, at Burlington House. For the Royal service 30 gentlemen entered their names for 10 appointments; 20 competitors for the Navy, 10 vacancies; 40 candidates for the Indian Medical Service, 8 vacancies.

Surgeon-Major D. Sinclair, Madras Medical Service, officiates as Inspector-General of Prisons in Burmah, vice Surgeon-Major Kelly.

Surgeon-Majors C. Harvey, Dallas, Edge, Beattie, Williamson, Carey, Surgeon Huey, Madras Sappers and Miners, and Surgeon Elmes, have embarked at Bombay for duty with the Indian contingent for Egypt.

Surgeon-Major Jazłowski, Surgeons Lane and Irvine, embarked on board H.M. ship *Malabar* on Saturday last, in charge of the troops proceeding to Egypt.

**ARMY MEDICAL DEPARTMENT.**—Surgeon-Major Alexander Robert Hudson, M.B., has been granted retired pay, with the honorary rank of Brigade Surgeon; Surgeon-Major Charles Henry Browne has been granted retired pay, with the honorary rank of Brigade-Surgeon.

**ARTILLERY VOLUNTEER CORPS.**—3rd Durham: Surgeon Joseph Frain is granted the honorary rank of Surgeon-Major.—8th Lancashire: Thomas Bushby, Gent., to be Acting Surgeon.

**RIFLE VOLUNTEERS.**—1st Durham: Joseph Whitfield Blandford, Gent., to be Acting Surgeon.—22nd Lancashire: Surgeon Thomas Fort, from 7th Lancashire Rifle Volunteer Corps, to be Surgeon.—3rd Monmouthshire: Octavius Edward Bulwer Marsh, Gent., to be Acting Surgeon.

**ADMIRALTY.**—The following appointments have been made:—Staff Surgeon William Roche to be Fleet Surgeon in Her Majesty's Fleet, with seniority of August 13th; Surgeon Francis Williamson has been placed on the Retired List of his rank from August 4th; Staff Surgeon George Kell, to the *Vernon*, vice Roche; Surgeon John Ottley, to the *Starling*; Staff Surgeon Anthony Gorham, to the *Hercules*, vice O'Callaghan, M.D.

## THE ARCTIC EXPEDITION IN THE "EIRA."

MR. W. H. NEALE, M.B., B.S., medical officer of the *Eira*, has favoured us with the following special medical report:—

I am afraid there is very little to say, in a medical point of view, with regard to the late Arctic expedition of Mr. Leigh-Smith, its great characteristic being the singular absence of disease amongst a crew of twenty-five men during a sojourn of fifteen months in the Arctic regions. Two men were under treatment the whole winter; both of them were invalids before the *Eira* sailed in 1881, and would not have been amongst the crew if they had been obliged to pass a medical inspection before signing articles. One man injured his right forearm in July, 1881, but neglected to dress it, or to mention the accident to anyone; he again injured it in September, 1881, and after suffering some days with it, he came to me and showed me a sorry sight: the whole of the forearm was covered with eczema, his shirt had become dried to the inflamed skin, and several small ulcers were developed. Another man had a small ulcer on the lower lip, which I noticed before we sailed, and tried to dissuade him from starting from Peterhead, but he said the lip had been bad for more than a year, and three months' cruise would do no harm. Fortunately it was not until the spring of 1882 that the growth began to increase to any extent, but during the last two months he became so much worse that I fear he is now beyond all medical or surgical treatment. A case of stricture in a man aged forty-six years gave me a little anxiety once or twice during the winter, as I had lost all my catheters, but fortunately he never had retention more than a few hours. I may here mention that the medicine chest was saved.

When we first began to eat the walrus and bear flesh nearly everyone had diarrhoea; some of the men became

very weak, and in one case the diarrhoea continued five or six days in spite of treatment, and reduced the man to such an extent that he lay down and made up his mind to die. After having lived on the meat for two or three weeks everyone began to recover, and soon all were as regular with regard to the bowels as if they had been enjoying the comforts at home. There was, however, a tendency to constipation, and in the spring many of the men had slight hæmorrhage; the fæces were always almost quite black. Small cuts and slight frost-bites were common; no frost-bites ever caused any serious injury, but a cut, however small, took weeks to heal unless the greatest care was taken to keep the frost away from it when out of doors.

Medical cases were very rare; one man had an attack of bronchitis, followed by pleurisy of the right side, but was only confined for three weeks to the house; another had bronchitis which kept him in bed about a fortnight.

Almost everyone was affected with snow blindness in the spring; no cases were severe. The conjunctivæ were inflamed, the eyes ran with water, there was the greatest intolerance to light, and, in the majority of cases, severe shooting pains over the frontal regions. A lotion of sulphate of zinc (one grain to one ounce) gave great relief in many cases where there was much inflammation. If great intolerance to light was the chief symptom, two or three drops of solution of atropine dropped into the eye once or twice a day soon restored the eyes to their normal state. In cases of severe shooting pains in the head, a few drops of diluted wine of opium always gave great relief. No case had to remain in the house more than forty-eight hours, and no one sustained any permanent injury to their sight.

Our hut was built of stone and turf; it was 38 ft. long, 12 ft. broad, and 4 ft. to 7 ft. high, the walls 3 ft. thick. Inside it was divided off into three compartments by means of canvas curtains; one part, 19 ft. long by 12 ft. broad, served as the forecabin; in this twenty men slept; the middle compartment, 10 ft. by 12 ft., was the kitchen, and the third compartment, 9 ft. by 12 ft., was reserved on one side for Mr. Leigh-Smith and myself. In this place all the wines, spirits, tea, &c., were kept, while on the other side the ice-master and two mates (our two invalids) had their beds. A porch (17 ft. long, 4 ft. high, and 3 ft. broad, with a single piece of canvas, at the inner end of which was our only door) was built, and the fireplace was erected opposite to it. The roof was made of sails. Ventilation was very free near the porch, but we had several ventilators in the roof, made of old provision tins, to which lids were fitted, so that they could be closed during heavy snow or excessive frost. The temperature inside the house varied from 35° to 45° F. during the day in the kitchen, but at night it was often four or five degrees below freezing point. The temperature of 20° F. was considered warm in our sleeping compartment. Many a time 0° F. was registered on the ground in the kitchen. Outside the thermometer could only register - 43° F., and the temperature was often below that for hours. Our clothing was scanty, consisting of woollen and flannel garments, no skins or furs of any kind were worn, and I do not think they are necessary, unless one is sledging or obliged to go out in all weathers to make observations. Washing was a luxury seldom indulged in during the winter, and a clean change of clothes once in three months was considered a great piece of extravagance. No trace of vermin could be seen on anyone, though I searched closely several times, especially in the spring, when nearly everyone complained of terrible irritation, particularly at night; it only lasted three or four days, and, I believe, was due to the fact that one of the bears we killed had a sore foot with a large suppurating gland in the axilla. The blood had been saved and mixed with our stock of blood before the sore was detected; being rather short of provisions the blood could not be thrown away, and we ate the flesh of the bear, bad leg included (unknown to myself). Our food consisted chiefly of bear and walrus meat, mixing some of the bear's blood with the soup when possible. The allowance of meat per day fluctuated from 25 lb. to 50 lb. for all hands, but the whole time we were able to have about 12 lb. of vegetables per day, divided amongst the three meals, and from October 1st to May 1st every man had, daily, a quarter of a pound of flour with his dinner, made into a "dough boy."

For the boat journey we saved 40 lb. of tinned meat (per man), and 35 lb. of tinned soups (per man), 3 cwt. of biscuit, and about 800 lb. of walrus meat, which was cooked and soldered up by our blacksmith in old provision tins. About 80 lb. of

tea were saved, enabling us to have tea night and morning till almost the day we were picked up. No lime-juice was saved. A few bottles of wine and brandy were secured, and kept for Mr. Leigh-Smith and invalids. All the rum was saved, and every man was allowed one-fifth of a gill per day until May 1st, 1882, when it was decided to keep the remaining eighteen gallons for the boats. One man was a teetotaler from January to June, and was quite as healthy as anyone else. Personally it made very little difference whether I took the allowance of "grog" or not. One of the sick men was also a teetotaler nearly all the time. During the boat journey the men preferred their grog when doing any hard work, a fact I could never agree to, but when wet and cold a glass of grog before going to sleep seemed to give warmth to the body and helped to send one to sleep. Whilst sailing, also, a glass of grog would give temporary warmth; but everyone acknowledged that a mug of hot tea was far better when it was fit weather to make a fire. I do not think that spirits or lime-juice is much use as anti-scorbutics; for if you live on the flesh of the country even, I believe, without vegetables, you will run very little risk of scurvy. There was not a sign of scurvy amongst us, not even an anæmic face.

I have brought home a sample of bear and walrus meat in a tin, which I intend to have analysed if it is still in good preservation; and then it will be a question as to how it will be best to preserve the meat of the country in such a form as to enable a sufficient supply to be taken on long sledge journeys; for as long as you have plenty of ventilation and plenty of meat, anyone can live out an Arctic winter without fear of scurvy, even if they lie for days in their beds, as our men were compelled to do in the winter when the weather was too bad to go outside (there being no room inside for more than six or seven to be up at one time).

## WILLS AND BEQUESTS.

THE will and codicil of William Cheyne Wilson, M.D., of 19, Tamar-terrace, Stoke, Devon, who died on May 6th last, were proved on the 1st inst. by Mr. David Wilson, the brother and sole executor, the value of the personal estate being over £1600. The testator leaves all his real and personal estate to his wife, Mrs. Sarah Wilson, but, in consequence of her death, his property becomes divisible between his children.

The will of Dr. John Cotton, Deputy Inspector-General, R.N., of the Royal Naval Hospital, Plymouth, who died on the 12th ult., was proved on the 7th inst. by Mr. George Mitchell, one of the executors, the value of the personal estate exceeding £7000. The testator gives to his wife, Mrs. Katherine Cotton, £200 and all his household furniture and effects; and the residue of his estate he leaves upon trust for his wife for life or widowhood, and on her death or marriage again for his daughters Marie and Katherine Lucy.

The will of Major Richard Culverwell, M.D., formerly of Arundel-street, Strand, but late of Springfield-road, St. John's-wood, who died on January 16th last, was proved on the 12th inst. by Mr. Charles Culverwell, the son and executor. The testator, in referring to certain arrangements as to his property, made by him in his lifetime, speaks of the love, kindness, and generosity towards him of his said son, "professionally known as Charles Wyndham, comedian." There are two or three legacies, and the residue of his property he divides between his four children.

The will of Thomas Oliver Duke, surgeon, of 87, High-street, Clapham, who died on June 5th last, was proved on the 4th inst. by Benjamin Duke and Edgar Duke, the sons of the deceased and acting executors, the value of the personal estate amounting to over £19,000. The provisions of the will are in favour of the testator's children; he leaves the goodwill of his practice to his sons Benjamin, Maurice Smet, and Edgar.

The will of Edward Doubleday, M.D., of Dovecote House, Long Clawson, Leicestershire, who died on June 10th last, was proved on the 16th inst. by Mr. Robert Bianchi and Mr. Edward Doubleday, the acting executors. There are numerous bequests to his own and his late wife's relatives and others, the principal legatees being his nieces, Mrs.

Catherine Bianchi and Miss Annie Croft Doubleday, and his two nephews, both named Edward Doubleday.

The following legacies have recently been left to hospitals and other medical charities:—Mr. Antonio Alexander Ralli, of 102, Westbourne-terrace, Hyde-park, and of 9, Gracechurch-street, £250 each to the Hospital of the Island of Scio, and the special hospital for the leprosy in the same island.—Mr. David Berlandina, formerly of 80, Old Broad-street, merchant, but late of Villa Abbo, Rue Cotta, Grimalli, Nice, twelve guineas each to the Hospital for Spanish and Portuguese Jews, Mile-end-road, and the London Hospital, Devonshire-square. Mr. Henry Howell, of Old-street, 100 guineas to the Royal Hospital for Diseases of the Chest, City-road.

## Correspondence.

"Andi alteram partem."

### THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—It appears from the resolution passed at the meeting of Fellows, held at Worcester on the 10th inst., that the annual meeting of the Association of Fellows is to "be held at and during the annual meeting of the British Medical Association." This implies that the Association of Fellows of the Royal College of Surgeons of England, like the New Sydenham Society, will become an appanage of the British Medical Association. As there are many Fellows of the College who deliberately stand aloof from the British Medical Association, and will continue to do so, unless the management be effectually reformed, the meetings of the Fellows' Association cannot be truly representative.

While I heartily approve of the formation of an Association of Fellows, I maintain that London is the most convenient place in which to hold its annual meetings, and the beginning of July the fittest time, when the Council elections take place. This arrangement possesses the further advantage that provincial Fellows would have an additional inducement to come to the metropolis to record their votes, thereby quickening their interest in the affairs of the College.

I am, Sir, yours, &c.,

Harley-street, Aug. 21st, 1882.

JOHN TWEEDY.

### WHAT HINDERS NOTIFICATION OF INFECTIOUS DISEASE.

To the Editor of THE LANCET.

SIR,—In replying to Dr. Jones's letter in THE LANCET of August 19th I distinctly state that I did not attack him through his official position, and therefore wish to avoid any personality or insinuation, my reason for writing to you being to show one unfortunate feature in the working of the Compulsory Notification of Infectious Diseases Act. June 20th was the first day that I or any of my colleagues became aware that the Blackpool Corporation would supply carbolic oil gratuitously when required. Neither were we aware that the medical attendant was expected to state the time for the cleansing and disinfecting of houses to the sanitary authority, knowing that we had no authority, and considering this an important part of the duties of the medical officer of health. I was once just in time to prevent a sanitary servant from burning sulphur in a house three days after the commencement of a case of measles complicated by pneumonia.

Isolation by accommodation in the sanatorium infers payment varying from half a guinea to a guinea per week for each person (patient or nurse) from the party responsible to the Corporation. But in this case the responsible party preferred nursing the child at home, where the isolation would have been nearly as complete; for I forbade anyone to be admitted into the house, and was "only glad to escape odium" by advising the father to continue to ply for hire, but live away from, and not come into, his own house. The wife told me that the inspector said that her husband might please himself whether he drove on the 18th or not,

but that she said that would not satisfy her, and he then gave his consent to the man driving again.

Regarding "a pure invention of somebody's," it is immaterial, so far as the principle is involved, whether a prescription, a written or a verbal order was given to the patient's mother for the carbolic oil. It actually was, I find, a verbal order; but I was misled by the inspector bringing me the prescription from the chemist, but was particularly careful to place in my last letter the words, "For scarlet fever patients only," to show that the prescription was a general one.

Regarding "MacDonald's just cause of complaint against me," I had to decide between his word and that of the mother, supported by her sister, &c., who could not have any motive for saying what was not true; and I still believe what they said and signed.

I agree that the Legislature would act wisely to insist that a medical officer of health should not be allowed to practise, but have a district large enough to provide sufficient work, sufficient pay, and security that he will not be thrown out of office because of personal spite or jealousy. Such legislation, if the Compulsory Notification Act ever becomes general, will prevent a vast amount of unpleasantness, misunderstanding, and unfairness such as we fancy we have experienced in Blackpool; and the Act will not have the hearty co-operation of general practitioners unless they be taken into confidence, and the householder be as liable to a heavy fine as they themselves for not reporting infectious disease existing in his or her house.

I am, Sir, yours truly,

Blackpool, Aug. 21st, 1882.

WM. B. RICHARDSON.

### "SCURVY."

To the Editor of THE LANCET.

SIR,—A propos the annotation appearing under the above heading in THE LANCET of June 24th, pp. 1048-9, I would beg permission to observe that almost every medical man in India will be able to endorse the views of Dr. Moore, to which you refer. Medical officers of native regiments notice almost daily in their hospital practice that—to use your writer's words—"insufficient diet will cause scurvy even if fresh vegetable material forms a part of the diet, though more rapidly if it is withheld." Indeed, so far as my humble experience as a regimental surgeon from observations on the same men goes, I am inclined to think that the meat-eating classes of our Sepoys—to wit, the Mahomedans, especially those from the Panjab—are comparatively seldom seen with the scorbutic taint; while, on the contrary, the subjects are, in the main, vegetable feeders who are their non-meat-eating comrades, the Hindus (Parboos from the North-West Provinces and Deccan Mahrattas), especially those whose daily food is barely sufficient either in quality or quantity. A sceptic may refuse to accept this view on the ostensible reason that though the food of the meat-eating classes be such, it may, perchance, contain vegetable ingredients as well as meat. To this I would submit the rejoinder that as a matter of fact, quite apart from all theory and hypothesis, the food of these meat-eating classes does not always contain much, or any, vegetables. In the case of the semi-savage hill tribes of Afghanistan and Baluchistan, their food contains a large amount of meat (mutton), and is altogether devoid of vegetables. The singular immunity from scurvy of these races has struck me as a remarkable physiological circumstance, which should make us pause before accepting the vegetable doctrine in relation to scurvy *et hoc genus omne*. Those of our medical brethren who have had opportunities of observation in those dismal and dreary wilds will agree with me when I say that there are other causes at work which go a long way to produce this diathesis, certainly quite irrespective of the question of the absence or insufficiency of the vegetable element in the food. Pressure on my time, and perhaps also the space in your columns, will not permit of my entering here at length into this important physiological question; but suffice it to remark in brief that these are:—

1. Monotony or sameness of the diet and manner of cooking and preparing it, without much change, or, indeed, any change whatsoever, as was the case with the "field ration" issued to the troops there. The Europeans got potato as the (sole) vegetable, sometimes bad, while the

natives got neither vegetables nor meat. Here I may simply refer to the case of the diet question of convicts of Indian prisons, which has recently excited considerable controversy both in the lay and in the medical press and in Parliament. I, in common with everybody else who has read and studied his report, am entirely in accord with Dr. Cunningham when he writes ("Seventeenth Annual Report of the Sanitary Commissioner with the Government of India," 1880) that there are other causes at work in prisons to account for ill-health, including scurvy, beside the "Conference" diet, to which all the blame appears to be attached by most reviewers of that publication. The excellent scientific report by Dr. Lewis ought to satisfy the critical analyst. In the case of the troops in Afghanistan, I believe the scorbutic taint existed largely in both Europeans and natives, though it was more marked in the latter.

2. *Ennui*, with absence of surroundings calculated to stimulate and cheer the mind, and the existence of almost everything likely to depress it to a degree, such as was the case there; prolonged stay in the same uninteresting places, with the same identical, forsooth dismal, scenes.

3. Harassing and arduous duties, or absolute idleness, under the above-mentioned circumstances.

The monograph by Dr. Robert Moodie, late of the Indian Medical Service, now practising at Stirling, is a most interesting contribution on the subject of scurvy, the outcome of observations by an accomplished physician who in the late Afghan war availed himself of the opportunities which presented themselves. To it I would beg to invite the attention of my professional brethren.

I am, Sir, yours truly,  
Ahmedabad, July 11th, 1882. JOHN C. LUCAS.

## SULPHIDE OF CALCIUM IN CANCER.

*To the Editor of THE LANCET.*

SIR,—The distressing and fatal nature of cancer in its various forms prevents my offering to the profession any apology for bringing before their notice the sulphide of calcium as a therapeutic agent in the treatment of the disease. In doing this, I wish to state that I do not claim for the remedy any completely curative power without operation; still, in several cases which have been treated by me without operation, the drug certainly seems to have had more effect than any other with which I am acquainted in retarding the growth of the malady.

I was first induced to try sulphide of calcium about three years ago, after having read Dr. Ringer's article on that remedy in his *Handbook of Therapeutics*.

The first case in which I tried the sulphide was that of E. S—, aged thirty-four years, the wife of an agricultural labourer. She had suffered from cancer of the breast for about twelve months, and persistently refused to undergo an operation until she saw death from the disease was inevitable. I undertook the operation at her own request, with the view of prolonging her life, and in favour of her infant child, but without any hope of her ultimate recovery. When admitted into our cottage hospital she was much emaciated, and the cancerous cachexia was decidedly marked. Nearly the entire breast was affected, the nipple retracted, and the skin adherent. The growth was very hard and nodular; superficial veins large and dark; glands in the axilla enlarged; and there appeared to be nothing wanting to complete a correct diagnosis of the disease, which was confirmed by four medical men. The entire breast was removed, under chloroform, the wound treated in the usual manner, and the patient made a rapid recovery. She gained flesh in a remarkable manner, and went out of the hospital quite well and strong, and remains so to this day. She has, since the operation, had another child. She was in hospital two months. I commenced to give her one grain of the sulphide daily on admission. In a few days this was increased to three grains a day, and continued for three months.

The second case was that of J. F—, aged thirty-five, unmarried. She had for some months a hard scirrhous lump under the right nipple, which was very painful, and greatly increased whilst she was nursing a brother through a severe attack of enteric fever. I will not enter into the details of the case further than to state that my diagnosis was confirmed by two or three medical men, one of whom is

a visiting surgeon of the Lincoln County Hospital, and he was present at the operation. This patient was kept under the sulphide of calcium treatment some months, and is quite well, without a trace of the disease being left.

The third case is that of E. N—, aged thirty-five years, a widow, a laundress, and mother of seven children. She had suffered for some months from a hard, painful, and increasing lump in the right breast; had been losing flesh for twelve months, and was much exhausted. Her mother's sister had died from cancer. I amputated the breast at the cottage hospital under chloroform. The patient bled very profusely, and was taken from the table very much blanched. Her recovery was remarkable; she gained flesh and strength very quickly, and in a manner which surprised me, and she has since married, and expresses herself quite well. She left the hospital in December last. She was kept for four months under the sulphide treatment. I may say that the diagnosis of this case was confirmed by three other qualified men.

I publish these cases in the hope that the remedy which certainly appears to have been of service in my hands may be of still greater benefit in the hands of others.

I am, Sir, yours truly,  
EDWIN W. BARTON, M.D. Brus., L.R.C.P. Lond.  
Market Rasen, Aug. 21st, 1882.

## FAT EMBOLISM IN DIABETES.

*To the Editor of THE LANCET.*

SIR,—May I crave space to correct your brief notice of my remarks in the discussion on diabetes in the Pathological Section at Worcester? You report me to have said that I had found very few fat emboli in my cases of diabetic coma. What I did say was that I had found no true fat emboli in a case of diabetic coma in which the blood was extremely fatty; and I referred to the paper by Dr. Barling and myself in the July number of the *Journal of Anatomy and Physiology*, in which we showed that the fat merely collected in globules of less size than the lumen of the vessels, and lay embedded in the post-mortem thrombi. I also drew attention to the frequency of fat emboli in fractures, and to the absence of symptoms in these cases, unless the emboli were extremely numerous. I am, Sir, yours faithfully,  
Birmingham, Aug. 19th, 1882. ROBERT SAUNDY, M.D.

## COTTAGE HOSPITALS.

*To the Editor of THE LANCET.*

SIR,—You suggested in an article some time ago that it was desirable that each Cottage Hospital committee should contribute in its corporate capacity a small sum, in no case exceeding £5, to the Napper Testimonial Fund. Some of the hospitals appear to take up this suggestion warmly, but I regret to say that as a matter of fact not a single cottage hospital in its corporate capacity, of the whole of the three hundred and twenty at present existing in this country, has sent one penny to the Napper Fund. I have taken a considerable interest in cottage hospitals, and have done my best to promote their efficiency and success. For this reason, perhaps, I not unnaturally feel zealous for the honour of these useful institutions, and I desire to ask the members of the medical staff of cottage hospitals throughout the country to bring the subject of the Napper Testimonial before an early meeting of their committee with the view of ascertaining if any, and what, contribution shall be given to it. Personally it is not the amount which I shall value, and a subscription of even five shillings would be regarded by me with satisfaction as evidence that great public services rendered by an exceptionally able and good man were not forgotten by those who have most benefited by them. I urge the medical men in question, and I earnestly beg of all of them with whom I am personally acquainted to remove this slur from the escutcheon of cottage hospitals by showing at once that in the case of those which are best managed, at any rate, gratitude is not a lively expectation of favours to come. Let each member of the medical profession resident in the country ask himself what he owes to Mr. Napper, whose foresight originated, and whose invariable readiness to give substantial help and information secured the success, of the majority at any rate, of the cottage hospitals which are scattered throughout the country to-day. It is, of course, a

matter within the discretion of each committee to decide whether the subscription to the Napper Testimonial Fund shall be contributed out of the funds of the hospital or the private purses of its staff and the committee. For my part, I believe it will be best that each member of the staff and committee of every cottage hospital shall be asked to subscribe 1s., and that the total sum so raised should be sent to the Treasurer of the Napper Testimonial Fund, Mr. Malcolm Morris, F.R.C.S., 63, Montague-square, Hyde-park, as the contribution of the — Cottage Hospital. If the testimonial fund is closed without the receipt of a single contribution from any cottage hospital in this country, I am bound to state that in my opinion such a result will redound to the discredit of every cottage hospital in the country.

I am, Sir, your obedient servant,

HENRY C. BURDETT.

Gloucester-road, Regent's-park, N.W., Aug. 23rd, 1882.

## SCOTTISH NOTES.

(From our Correspondent.)

PROSECUTIONS for the sale of unsound meat are rare in Scotland, and a case tried in Aberdeen a few days ago excited some interest. Dr. Robertson stated that the animal suffered from tubercular disease, and was unfit for food, while for the defence the disease was stated to be "inberries," which was common in healthy animals. The court accepted the medical evidence. A good deal of uncertainty is felt in carrying out the law on this important subject, and the sanitary inspectors and veterinary surgeons (often unqualified), who are generally first consulted, seem to give very conflicting decisions. It is not uncommon to find the fore-quarters of an animal which has suffered from tuberculosis condemned, while the hind-quarters are sent for sale. The difference between local and general disease seems hazy to the inspector, and it would be but fair, alike to the public and the owners of suspected animals, that only properly qualified veterinary surgeons or medical men should have the decision placed in their hands.

A gentleman has just died at Innerleithen from the results of a peculiar accident. It appears that two months ago, while lying upon his back, he had fallen asleep by the river side where he had been fishing. On awaking he found that the gold plate, with five teeth attached, had slipped from the upper jaw into the throat. Unsuccessful efforts were made at extraction, and the plate was then pushed downwards to avoid suffocation. He was under observation for some weeks at the Edinburgh Royal Infirmary, but lately returned home, not having got rid of the intruder. The ultimate cause of death appears to have been blood-poisoning, but a medical record of the case would be interesting.

From various quarters lately I have noticed a corroboration of what might be called THE LANCET views with regard to the proper treatment of the insane. Passing over the powerful arguments of Professor Gairdner last week in Glasgow, I notice in some asylum literature the rise of opinions in favour of such increased liberty and early removal from asylum influences as must be satisfactory to you. The Fife and Kinross Asylum seems to offer a good example of what a careful weeding process may effect, as Dr. Turnbull has been able there to relieve the overcrowding, which was rapidly determining the necessity for further extension, and during the year to reduce the number of inmates by thirty, the total number remaining being 345. From the statistics given by Dr. Sibbald, Commissioner in Lunacy, it appears that great disparity exists in different counties in the amount of accommodation provided for pauper lunatics; and as the general cry is for more room, doubtless directors of asylums will pay due heed to the method of overcoming the difficulty which is now suggested by the action of Dr. Turnbull. The annual report of Murray's Royal Asylum, presented by Dr. Urquhart, also gives ample evidence of thoughtful and judicious management. He is anxious to get patients at as early a stage as possible, and his statistics of cases so received are very encouraging. He states that "every year leads us further from the ideal madhouse, and nearer the ideal hospital," protests against

the silting up of asylums by chronic and incurable cases, and states that "the asylum is not always the best place for the unrecovered patient." Over fifty per cent. of the patients are on parole, many of them without the walls, several are allowed to visit their friends in different parts of the country, and seaside residence is allowed to those thought likely to be benefited. Dr. Urquhart has still a favourable word, in suitable cases, for the almost obsolete weapon, the box-bed.

A medical student named W. B. Austin was last week remitted from one of our police courts on a charge of having administered noxious drugs to a servant girl for the purpose of procuring abortion.

The Gilchrist trustees have arranged with the following well-known gentlemen to deliver a course of lectures in various towns in Scotland during next winter:—Dr. Carpenter, Mr. W. L. Carpenter, Mr. W. M. Dollinger, Dr. Martin Duncan, Mr. R. A. Proctor, Professor Balfour Stewart, Professor Williamson, and Dr. Andrew Wilson.

## PARIS.

(From our Paris Correspondent.)

It is well known that the digestion of different kinds of meat is the more easily effected the longer the time that transpires after the death of the animal. The explanation given is, that by keeping the muscular fibres become gradually dissociated; they soften, become less compact, and consequently are more soluble in the gastric juice. According to physiologists, however, it is not considered advisable to wait until decomposition sets in, because in addition to its losing a great part of its nutritive qualities, the meat becomes so nauseous that no amount of cooking, or the addition of condiments, will much improve it. M.M. Pasteur and Lemaire, in an interesting paper lately submitted by them to the Academy of Sciences, stated that meat too far advanced, or what is termed "faisandée," is most unwholesome, and it is a mistake committed daily by sportsmen to wait until the game gets into this condition, for it is then simply unfit to be eaten. The above-named biologists have shown that tainted meat contains animalcules, which do the work of transformation and destruction; and as it is difficult to ascertain exactly the extent of putrefaction that the meat has undergone one is liable to consume it just at the moment when it should be rejected. M. Pasteur and other micrographers are of opinion that these animalcules, of which there are no less than thirty species, are of the same nature as those that are found in living animals suffering from virulent maladies, such as charbon, &c.

M. Jules Guérin, who is approaching his eightieth year, is publishing the most important part of his literary works, extending over a period of more than half a century. It is appearing in periodical numbers, the fourth of which has just come out, and contains a complete study of congenital deformities in the fœtus and children, which is a continuation of his researches on the congenital deformities in monsters. A great portion of the present number is devoted to numerous observations in support of the author's theory as to the causes of deformities existing before and after birth, as, according to M. Jules Guérin, the causes which were in operation before birth may be found after it, and they produce identical effects in both cases. It is known that there exists a difference of opinion among teratologists as to the causes of congenital monstrosities and deformities, some of them being founded on the organic or pathological condition of the parents acting on the child, and thus giving rise to hereditary abnormalities, to diseased varieties, and to the degradation of the descendants. They are also attributed to an unknown organic arrangement of the elements of conception. The effects of the imagination of the mother on the different accidents that occur during pregnancy are also mentioned in classical works, but this latter theory is, of course, now no longer accepted by teratologists. Finally, organic or structural abnormalities of the embryo have been ascribed to arrest of development, either primary or secondary, and it is to these causes that M. Jules Guérin attributes the greater part of congenital monstrosities and deformities. In fact, M. Guérin thinks

<sup>1</sup> Two hundred and forty-seven of Dr. Turnbull's patients are industrially employed,—a very satisfactory proportion.

that all these deformities may be attributed to the operation of the same causes.

Dr. Debove is persevering in his praiseworthy efforts to feed patients who cannot or will not eat, such as insane patients, or those who have gastric troubles. He had already designed various means to carry out his object, not only in the way of instruments, but to have the food to be administered in the most concentrated form. At a recent meeting of the Société Médicale des Hôpitaux, Dr. Debove submitted a special œsophageal sound, which patients may introduce, and thus feed themselves with any appropriate nourishment. Physicians have doubtless met in their practice patients subjected to a milk diet who get tired of it after a time. To obviate this inconvenience, Dr. Debove employs the powder of milk which he obtains by desiccation, having previously removed the cream, which is difficult to digest. He administers the powder in a little warm milk; and he stated at the meeting that he has employed it with great success in the treatment of simple ulcer of the stomach. Each packet of the powder contains 120 grammes, which are equivalent to one litre of fresh milk. Dr. Dujardin-Beaumetz has used Dr. Debove's milk-powder mixed with the powder of meat, both being dissolved in ordinary milk, and he has thus kept up for some time the strength of several of his phthisical patients.

Dr. Quesneville has succeeded in preserving water potable by adding to it three centigrammes of salicylic acid to the litre. He related at the Société d'Hygiène that he had thus preserved a bottle of water for more than three years. It may be of some importance to know this at the present moment, as it may be found useful for the Egyptian expedition, where a dearth of water is apprehended.

Paris, Aug. 22nd, 1882.

## Medical News.

UNIVERSITY OF LONDON. — The following candidates have passed the recent Honours Examinations:—

### ANATOMY.

#### FIRST CLASS.

- \* Anderson, G. Elliott Caldwell, Guy's Hospital.
- † Innes, Chas. Barclay, St. Bartholomew's Hospital.
- Woolbert, Henry Robert, University College.

#### SECOND CLASS.

- Robinson, Hy. Betham, St. Thomas's Hospital.
- Brock, Jas. Harry Ernest, University College.

#### THIRD CLASS.

- Flemming, Percy, University College.
- Carr, John Walter, University College.
- Watson, Wm. Ivens Baswell, Guy's Hospital.
- Cooper, Henry Chas. Evans, Guy's Hospital.

### MATERIA MEDICA AND PHARMACEUTICAL CHEMISTRY.

#### FIRST CLASS.

- \* Carr, John Walter, University College.
- Eq. † Innes, Chas. Barclay, St. Bartholomew's Hospital.
- Woolbert, Henry Robert, University College.
- Flemming, Percy, University College.

#### SECOND CLASS.

- Whitcombe, Philip Percival, St. Mary's Hospital.

#### THIRD CLASS.

- Brock, Jas. Harry Ernest, University College.
- Eq. † Havman, William Speed, King's College.
- Randell, Reginald Maurice H., Guy's Hospital.

### ORGANIC CHEMISTRY.

#### FIRST CLASS.

- \* Innes, Chas. Barclay, St. Bartholomew's Hospital.
- † Spong, Chas. Stuart, B.Sc., Guy's Hospital.
- † Dutt, Upendra Krishna, B.Sc., St. Mary's Hospital.
- Anderson, G. Elliott Caldwell, Guy's Hospital.

#### SECOND CLASS.

- Elliott, John, B.Sc., Owens Coll. and St. Barth. Hosp.
- Brock, Jas. Harry Ernest, University College.

### PHYSIOLOGY AND HISTOLOGY.

#### THIRD CLASS.

- Anderson, G. Elliott Caldwell, Guy's Hospital.
- Tratman, Frank, Bristol Medical School.
- Vernon, John Jas. Dean, Guy's Hospital.
- Eq. † Cooper, Henry Chas. Evans, Guy's Hospital.
- Randell, Reginald Maurice H., Guy's Hospital.
- Spong, Chas. Stuart, Guy's Hospital.
- Bowes, William Henry, Guy's Hospital.

- \* Exhibition and Gold Medal.
- † Gold Medal.

- ‡ Obtained the number of marks qualifying for a Medal.

UNIVERSITY OF ABERDEEN. — The following are lists of candidates who have received the Degrees specified:—

### DOCTOR OF MEDICINE.

- Ackroyd, George, Streatham.
- Atherstone, Edwin, London.
- Blomfield, Arthur Geo., Devon and Exeter Hospital.
- Boswell, Alexander, Ashbourne, Derbyshire.
- Brodie, William Hampden, Aberdeen.
- Burgess, Peter, Ballindalloch.
- Campbell, Colin M'Iver, Durham County Asylum.
- Clark, William, Orroroo, South Australia.
- Davison, Rashell Thomas, Battle, Sussex.
- Davy, John, Halifax.
- Durno, John, Kemnay.
- Elliott, Frederick Hawes, Andover, Hants.
- Hall, John George, Aberdeen.
- Harris, John, Newcastle, New South Wales.
- Liebstein, Herman John, London.
- Lyon, Adam Corbet, Rillington, Yorkshire.
- Macdonald, Coll. Reginald, Beith, Ayrshire.
- Macdonald, William, Inverness.
- \* MacWilliam, John Alexander, London Temperance Hospital.
- M'Connell, James Frederick Parry, Calcutta.
- Mukhopadhyay, Satish Chandra, Calcutta.
- Philip, James Allan, Mavisbank, Polton.
- Preston, Henry Tolver, Scanningley, Leeds.
- Purkiss, Arthur, West Brixton, London.
- Reid, William, Aberdeen.
- Spence, John Shepherd, Ballater.
- Thompson, Lavington Gray, Tasmania.
- Thomson, John, Kendal.
- Watson, John Coatsworth, Sunderland.
- Watt, Joseph, Kinnaird, Huntly.
- Webb, William Edward, Burnley, Lancashire.
- Welford, Charles Henry, Sunderland.

### BACHELOR OF MEDICINE AND MASTER IN SURGERY.

- Anderson, Thom's Cochrane, Murnoch, Banffshire.
- Barrett, John, Peninsular and Oriental Service.
- Blunt, Henry Brine.
- § Bremner, James, Grange, Keith.
- § Brito, Philip Sebastian, Ceylon.
- Collie, John William, Aberdeen.
- Collie, Robert John, Aberdeen.
- § Cran, Alexander, Cabrach, Banffshire.
- Cunningham, Albert George, Bristol.
- Davidson, James M'Kenzie, St. Domingo, Buenos Ayres.
- Duncan, Alexander, Torphins, Aberdeenshire.
- Eddie, Arthur William, Aberdeen.
- † Griffith, Thomas Wardrop, Aberdeen.
- Haig-Brown, Clarence Wm., Godalming, Surrey.
- Henderson, David, Watten.
- Hodgson, Joseph Willoughby, Brighton.
- Holmes, William Reid, Aberdeen.
- Jenkyns, John, Aberdeen.
- ‡ Knight, George David, Skene, Aberdeenshire.
- Le Motte, George Herbert, Guernsey.
- Lunan, William Smith, Aberdeen.
- Macdonell, James Alexander, Duftown.
- Mackie, Alfred Alexander, Aberdeen.
- Maxwell, Charles Mayne, Hobart, Tasmania.
- Masson, John, Banchoory-Ternan.
- M'Arthur, James Irvine, New Deer.
- § M'Kinnon, David Reid, Aberdeen.
- M'Lean, Alexander, Cull, Aberdeenshire.
- Middleton, James, Auchindoir.
- Morrison, Arthur Andrew, Aberdeen.
- Nicoll, James Robert, Rhynie.
- Petrie, James, Rhynie.
- Phillips, Henry Astley, London.
- Rennie, Arthur, Chatham, Canada West.
- Rattray, John Moysey, Aberdeen.
- Reid, Donald.
- Reid, John, Portsoy.
- Rigby, Charles Samuel Alfred, Preston.
- Robinson, Frederick William, Huddersfield.
- Ross, William Pyle, Aberdeen.
- Russell, Alexander Wilson, Insch.
- Sarkies, Carrapiet John, Calcutta.
- Scott, Benjamin, Aberdeen.
- Sinclair, William, Nigg.
- § Taylor, John, Stonehaven.
- Thomson, Thomas Pickthorn, Gartly.
- Walker, John, St. Vincent, West Indies.
- Weir, Richard Rose, Elgin.
- Will, John Kennedy, Cullen.
- § Wilson, James, Rhynie.
- Wilson, John Henry, Warwick.
- Woodman, John Dover, Wing, Bucks.
- Wright, Martensz James, Colombo.

- \* Highly commended for Thesis.

- † Received highest Academical Honours, and awarded the John Murray Medal and Scholarship.

- ‡ Received highest Academical Honours.

- § Honourably distinguished.

At the same time the following were certified as having passed all the examinations, but did not graduate:—

- Brown, Henry Herbert. | Huison, Francis Joseph.
- Leslie, John Tasman Waddell.

**APOTHECARIES' HALL.**—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on Aug. 17th:—

Corner, Mitthaw Cursham, Mile-end-road.  
Denning, Arthur, Newhall-street, Birmingham.

The following gentlemen also on the same day passed the Primary Professional Examination:—

Francis Henry Butler, St. Mary's Hospital; Samuel Brookfield, Newcastle-on-Tyne; George Sidney Gent, University College Hospital.

The following gentlemen passed the Primary Professional Examination on the 10th inst.:—

Charles G. Grimmer, St. Bartholomew's Hospital.

**HENRY SLADE, M.R.C.S.**, retired fleet surgeon, is reported to have committed suicide at Bodmin by severing some of the arteries in his right thigh.

In the year ending March 31st the Excise duty on medicine vendors was net £4688 15s., in addition to the stamp duty on patent medicines of £144,883 9s. 6d.

**MR. THOMAS SOUTHEE**, who on his resignation some short while ago had held the office of Secretary to the Kent and Canterbury Hospital for half a century, has been presented with a purse containing £230.

A FINE of £20 was imposed at the Mansion House last week on the London, Tilbury, and Southend Railway Company, for neglecting to properly cleanse certain trucks which had been used for the conveyance of cattle.

A CONVALESCENT HOSPITAL for Bolton is to be erected at Bromley Cross, Turton. In 1870 Mr. Stephen Blair, of the Mill Hill Bleachworks, left £20,000 for the purpose, with certain conditions which the trustees have now been enabled to fulfil.

THE Parisians have a readier method of dealing with milk-adulterators than that which obtains in this country. A posse of police lately waited the arrival of the morning's milk at Batignolles station in Paris, and after witnessing from behind a loopholed wall the interesting process of "watering," pounced upon the delinquents, whom, with their deteriorated wares, and a quantity of bicarbonate of lime, they carried off in triumph.

A CENTENARIAN.—A lady died last week at Golden Island, near Athlone, at the alleged age of 107 years. It is stated that she enjoyed good health, considering her age, until three years ago, when she became prostrate physically and mentally. During this time she was attacked with fits of sleeplessness, followed by sleep which lasted for three days and three nights. These attacks came on at tolerably regular intervals.

## Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning at the latest.

**ANDERSON, JAS. WALLACE, M.D., C.M.Glas., F.F.P.S.**, has been appointed Dispensary Physician to the Royal Infirmary, Glasgow.

**BLACK, DONALD CAMPBELL, M.D.Glas., L.R.C.S.Ed.**, has been appointed Extra Dispensary Physician to the Glasgow Royal Infirmary.

**BROCK, WILLIAM JOHN, M.B., C.M.Ed.**, has been appointed Extra Dispensary Physician to the Glasgow Royal Infirmary.

**BROWN, WILLIAM H. JONAS, M.B.Glas., L.R.C.P.Ed., L.R.C.S.Ed.**, has been appointed Medical Officer of Health for the Alnwick and Cunnongate Urban Sanitary District, vice McEwen, resigned.

**BRUCE, ROBERT CATHCART, M.B., C.M.Ed.**, has been appointed Medical Officer for the Swinefleet District of the Goole Union, vice East, resigned.

**BRYDEN, ROBERT THOMAS, L.R.C.P.Ed., L.R.C.S.Ed.**, has been re-appointed Medical Officer of Health for the Windhill Urban Sanitary District.

**CHEESEWRIGHT, JOHN FRANCIS, M.R.C.S.**, has been appointed Surgeon to the Rawmarsh, Dalton, and Thrybergh Division of the West Riding Police Force.

**COSGRAVE, E. MACDOWEL, M.D., L.K.Q.C.P.I.**, has been appointed Physician to Simpson's Hospital, Dublin, vice James Duncan, M.D., resigned.

**DOUGALL, JOHN, M.D., C.M.Glas., F.F.P.S.**, has been appointed Dispensary Physician to the Royal Infirmary, Glasgow.

**EDWARDS, OCTAVIUS, L.R.C.P.Lond., M.R.C.S.**, has been appointed Medical Officer for the Leominster District and the Workhouse of the Leominster Union.

**FRASER, ROBERT MCLEAN, L.R.C.P.Ed., L.F.P.S.Glas.**, has been appointed Medical Officer for the North and Central Districts of the Darlington Union.

**HOLLIES, GEORGE, L.R.C.P.Ed., L.R.C.S.Ed., L.S.A.Lond.**, has been appointed Medical Officer for the Southern District of the Warrington Union, Salop.

**LACY, ALEX. GAIRDNER, L.R.C.P.Lond., M.R.C.S., L.S.A.Lond.**, has been appointed Medical Officer for the Sunninghill District of the Windsor Union.

**LAMBERT, JOHN, jun., M.R.C.S., L.S.A.Lond.**, has been reappointed Medical Officer of Health for the Fareley Urban Sanitary District.

**LANGDON, J. WINKLEY, M.R.C.S., L.S.A.Lond.**, has been appointed Ophthalmic and Aural Surgeon to the Preston and County of Lancaster Royal Infirmary.

**LYS, FRANCIS DANIEL, M.R.C.S., L.S.A.Lond.**, has been appointed Medical Officer of Health for the Wareham and Purbeck Rural Sanitary District, vice Stainthorpe.

**MACGREGOR, ALEX. GIBSON, M.D., C.M.Aber.**, has been appointed Medical Officer of Health for the Wilsden Urban Sanitary District.

**MANSON, RICHARD TAYLOR, L.R.C.P.Ed., M.R.C.S.**, has been appointed Medical Officer for the West and North-West Districts of the Darlington Union.

**MIDDLEMISS, GEORGE, L.R.C.P.Ed., L.F.P.S.Glas.**, has been appointed Medical Officer for the South and East Districts of the Darlington Union.

**MILES, G. E., M.R.C.S.**, has been appointed Resident Medical Officer to the Northumberland House Asylum, N.

**PRATT, FREDERICK, M.R.C.S., L.S.A.Lond.**, has been appointed Medical Officer for the Northam District of the Bideford Union.

**RAWSON, EDWIN ELSWORTH, L.R.C.P.Ed., M.R.C.S., L.S.A.Lond.**, has been reappointed Medical Officer of Health for the Clayton Urban Sanitary District.

**RUNNALS, HARRY BOYLE, M.R.C.S., L.S.A.Lond.**, has been appointed Medical Officer for the Fifth District of St. Germans Union.

**SHAW, WILLIAM JOHN, M.B., C.M.Glas.**, has been appointed Extra Dispensary Surgeon to the Glasgow Royal Infirmary.

**WATTS, THOMAS F., M.B., C.M.Ed.**, has been appointed Medical Officer to Her Majesty's Convict Prison, Dartmoor.

## Births, Marriages, and Deaths.

### BIRTHS.

**ALLSHORN.**—On the 15th inst., at Dalston-lane, the wife of Adolph H. Allshorn, M.D.Ed., of a son.

**DUKE.**—On the 16th inst., at Cavendish-terrace, Clapham-common, the wife of Benjamin Duke, M.R.C.S., of a son.

**ENGLISH.**—On the 21st inst., at Fulham-road, S.W., the wife of T. Johnston English, M.D., of a son.

**FENN.**—On the 19th inst., at Portland-terrace, Richmond, the wife of Edward L. Fenn, M.D., of a son.

**FITZPATRICK.**—On the 12th ult., at Coimbatore, Madras Presidency, the wife of Surgeon-Major Fitzpatrick, of a daughter.

**KAY.**—On the 12th inst., at Bentley, Hants, the wife of W. Kay, Surgeon, of a daughter.

**KERR.**—On the 19th inst., at Grove-road, Regent's-park, N.W., the wife of Norman Kerr, M.D., F.L.S., of a daughter.

**LAWTON.**—On the 22nd inst., at High-street, Poole, the wife of Herbert A. Lawton, L.R.C.P.Lond., M.R.C.S., of a son.

**LEE.**—On the 17th inst., at Gwendwr-road, West Kensington, the wife of Dr. Lee, of a daughter.

**NICHOLLS.**—On the 9th ult., at Dominica, West Indies, the wife of H. A. Alford Nicholls, M.D., of a son.

### MARRIAGE.

**HALL—CAREY.**—On the 17th inst., at Spiddal Church, co. Galway, Henry George Hall, Surgeon-Major, Madras Medical Service, to Clara Sophia, eldest daughter of the late Dr. Samuel Orby Carey, of Glenelg, Adelaide, South Australia.

### DEATHS.

**DEAN.**—On the 14th inst., at his residence, Butler-street, Oldham-road, after a short illness, Octavius Dean, M.R.C.S., L.S.A.Lond., aged 48.

**EARLE.**—On the 15th inst., at Baroda, Bombay, Joseph Herbert Earle, Surgeon, Indian Medical Department, eldest son of Joseph Earle, M.R.C.S., of Brentwood, Essex, aged 28.

**JOHNSON.**—On the 17th inst., Richard Locke Johnson, M.D., M.R.C.S., of Bury-place, Bloomsbury-square.

**PAUL.**—On the 18th inst., at Torriano-cottages, Camden-road, N.W., Andrew Paul, A.B., M.B. Trin. Coll. Dub., in his 79th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments, and Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*We cannot prescribe, or recommend practitioners.*

*Local papers containing reports or news-paragraphs should be marked.*

*All communications relating to the editorial business of the journal must be addressed "To the Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

### THE STUDENTS' NUMBER OF THE LANCET

will be published on Saturday, September 9th. Those gentlemen holding official situations connected with Medical Institutions in the United Kingdom, who have not yet forwarded the necessary information to our Office for publication in that number, are earnestly requested to send it *without the delay of a single post*. It will be esteemed as a favour if the needed alterations be made on the slip forwarded from this Office, so that risk of error may be avoided in the course of perusing bulky prospectuses.

MEMORIAL BRASS TO SURGEON LONDON, A.M.D.,  
AT ST. BARTHOLOMEW'S HOSPITAL.

The following subscriptions, in addition to those acknowledged in THE LANCET of Oct. 22nd, 1881, and June 3rd, 1882, have been received:—

H. Bott, Esq., Brentford..	..	..	£0 10 6
A. Bowby, Esq., London ..	..	..	0 10 6
E. J. Burgess, Esq., Brentwood ..	..	..	0 10 6
C. S. W. Cobbold, Esq., M.D., Colney Hatch	..	..	0 10 6
C. E. Harrison, Esq., M.B., Grenadier Guards	..	..	0 10 6
Luther Holden, Esq., Ipswich ..	..	..	0 10 6
J. Mills, Esq., London ..	..	..	0 10 6
Norman Moore, Esq., M.D., London ..	..	..	0 10 6
C. Parnell, Esq., Forest-hill ..	..	..	0 10 6
S. T. Plumbe, Esq., M.B., Maldenhead ..	..	..	0 10 6
J. E. Ranking, Esq., M.D., Tunbridge Wells	..	..	0 10 6
J. W. Roughton, Esq., Streatham ..	..	..	0 10 6
W. E. Steavenson, Esq., M.B., London ..	..	..	0 10 6
A. F. Stevens, Esq., M.D., London ..	..	..	0 10 6
H. Taylor, Esq., M.B., London ..	..	..	0 10 6
R. Wharry, Esq., M.D., London ..	..	..	0 10 6
Andrew Duncan, Esq., M.D., Bengal Army..	..	..	0 10 0
H. Smith, Esq., M.B., London ..	..	..	0 5 0
W. L. Webber, Esq., London ..	..	..	0 5 0

C. E. HARRISON, M.B., NORMAN MOORE, M.D.  
JOSEPH MILLS, W. E. STEAVENSON, M.B.

August 22nd, 1882.

The memorial brass is now in its place in the Hospital Church of St. Bartholomew-the-Less.

*Dr. Bonnejoy (Lausanne).*—Our correspondent should address his remonstrances to the French *savant* who has suggested the system.

*Dr. Saundby.*—Next week if possible.

### MONSTROSITIES IN THE PUBLIC STREETS.

To the Editor of THE LANCET.

SIR,—The Act which your correspondent seeks is the Vagrancy Act, 5th Geo. IV., c. 83. This is still in force, and enacts the penalties to be extended to vagrants. Among these are included those who seek alms in the public streets by the exhibition of wounds or other deformities. I wrote to the Home Secretary this spring, pointing out the increasing number of these deformities in the streets of London, and in a second letter quoted the clauses of the Act which applies to them. My two letters brought the usual official reply that the matter should have attention. I cannot, as a non-professional man, speak of the effect upon the system, but I can testify to the distress which I have seen to follow from the sudden coming in contact with these poor creatures. I hope this matter will not be allowed to drop until some means be found of removing the evil to which you have called attention.

I am, Sir, your obedient servant,  
Hyde-park-street, W. August 22nd, 1882. GEO. CAWSTON.

### VACCINATION IN THE GERMAN ARMY.

ACCORDING to Professor Vogt, of Berne, the average number of deaths per annum from small-pox in the Prussian army during the last fifty-one years was nineteen. This number he considers to be sixty per cent. in excess of the mortality from that cause amongst the remainder of the population within the same period. He adduces this fact as a proof of the inefficiency of vaccination, but the *Gesundheit* remarks that the circumstance may be attributed to the injurious effects of the greater exertion of soldiers and to the inferior quality of their food as compared with that of the civil population, while the less careful treatment sometimes accorded them during sickness would not be devoid of influence upon their general health, the combination of these causes preventing the benefits of vaccination from being felt in the same measure as is shown in the remainder of the population. The same journal remarks that the excessive mortality from small-pox which was recorded during the Franco-German war is no definite proof of the inefficiency of vaccination, though the causes already named may have impeded its salutary action. The deaths in the German army during the campaign from small-pox were 143, or three times the normal rate, comparing the number of men engaged with that of the population of Berlin. The statistics of mortality from this cause amongst the French prisoners in Germany are of a similar character, and are treated in a like manner by the *Gesundheit*.

*Still an Old Subscriber.*—1. D traps in connexion with waterclosets are objectionable for several reasons. Their construction is such that they are necessarily calculated to favour the retention of solid excreta and other filth; the angles of the lead-work of which they are made soon become permanently filled in with a coating of offensive matter, and their shape is such that they are almost incapable of being efficiently flushed. In short, the D trap is little better than a small cess-pool in which filth is certain to accumulate; besides which, as a special form of trap, it is absolutely unnecessary. On the other hand, a simple syphon-bend answers all the purposes of an efficient trap, and it avoids nearly all, if not all, the sources of offensiveness attaching to the D trap.—2. We know of no work dealing with the subject precisely from the point of view named, but Willan's Handbook of Hygiene contains the materials required.

*M.R.C.S.*—Mr. Thomas resided in Leicester-place, Leicester-square. He was elected a Member of the Council in 1813, Court of Examiners in 1826, and twice filled the office of President of the Royal College of Surgeons of England. He died at Belmont, near Torquay, June 26th, 1846, aged seventy-eight.

*Omega* had better apply to the Secretary of the Brussels Graduates' Association, Dr. Pocock, 20, Golborne-road, W.

### "THE CAUSE OR CAUSES OF ACUTE TONSILLITIS."

To the Editor of THE LANCET.

SIR,—As the subject of quinsy is being ventilated in your journal, I thought it might be interesting to mention the facts of a case which has just been under my treatment. It was that of a man aged fifty-seven, who says he has been subject to quinsy since he was twenty. He has had quite twenty attacks, but has not had one for ten years till now. The cause of it this time seems difficult to arrive at, for he was on the sick funds of his club when the attack came on for some symptoms of apoplexy, and, beyond the anxiety brought about by his illness, there were no other causes likely to produce quinsy. His meals were regular to the minute, and he underwent no sort of exertion. As regards the treatment, I had a good opportunity of trying the salicylate of soda, which I gave in large doses at the commencement of the attack, but with no apparent benefit, as the disease ran its course to suppuration, when I opened it with a bistoury, and he got well rapidly. My reasons for sending this case are—1st, because of the man's age, fifty-seven; 2nd, because of the failure of the salicylate of soda; and, thirdly, because of the absence of the causes lately given in your journal as the most frequent in this disease; and to add that of predisposition as certainly one of the most important.—I am, Sir, faithfully yours,  
Pill, August 11th, 1882. A. H. BOYS, L.R.C.P. Ed.

To the Editor of THE LANCET.

SIR,—I omitted to mention in my last communication that I have often found quinsy associated with masturbation, and if, as I imagine, it is brought about by extra waste of nervous or muscular tissue, the co-existence of the two may be something more than accidental. I do not believe that quinsy is the direct result of cold, because, if it were, laryngitis would be a much more common accompaniment than it now is. As regards its being the result of general cold, I can most certainly say in my own case that since I have wrapped up less I have been a far less frequent sufferer. I have never in my life had a marked attack of rheumatism, and think this evidence will be corroborated by the greater part of those who are or have been afflicted with quinsy.

I am, Sir, your obedient servant,  
Kingston-on-Thames, August 23rd, 1882. F. P. ATKINSON.

P.S.—If "Tyro" will only put upon trial the treatment I suggested in THE LANCET some three or four months ago, I can promise him he will be perfectly well in four days, and that without fail on every occasion.

## THE CHEMICAL INGREDIENTS OF CIGAR-SMOKE.

IN the chemical laboratory of the Bremen Sanitary Administration various experiments have lately been made for the elucidation of the above subject. According to the results obtained, some of the ingredients of tobacco-smoke are productive of poisonous effects, such as carbonic oxide, sulphide of hydrogen, &c., besides nicotine. The last-named substance is the one from which injurious effects from the use of tobacco arise, as the other substances named are of a very fugitive nature, and exist in but limited quantities in tobacco-smoke. According to the theory propounded in the statement in question, the quantity of nicotine destroyed during smoking is but small, hence it accumulates in the unconsumed end, which contains a proportion of nicotine in inverse ratio to its own size, as the longer a cigar is smoked the greater is the quantity of nicotine in the remaining part.

**An Intending Competitor.**—The triennial prize given by the Royal College of Surgeons must be sent in on or before Saturday, the 30th of December; the subject of it is "The Relations between the Radicles of the Lymphatic System and Capillary Vessels." The subject for the Jacksonian Prize, to be awarded at the same time, is "Wounds and other Injuries of Nerves, their Symptoms, Pathology, and Treatment."

**An American Correspondent.**—We believe that Dr. Guy's paper will be published in the September number of the Statistical Society's journal, which may be procured at Messrs. Harrison's, Pall-mall.

## VENESECTON: WHY IS IT SO RARELY PRACTISED?

To the Editor of THE LANCET.

SIR,—I have lately read with great interest Dr. Wenwick's cases of cardiac disease, published in THE LANCET a fortnight since, where bleeding was so very beneficial, and I think many young medical men must wonder why venesection is so rarely practised at the present day when fifty years ago it was one of the commonest operations performed. Now, why is this? Why has the brandy-bottle taken the place of the lancet in the treatment of many diseases? Is it because our forefathers used the lancet too freely, and in some cases with fatal results (as the writings of Marshall Hall only too plainly show), or has the type of disease changed during the last half century? I strongly believe that diseases are changing in character, and that bleeding is not often required; yet I decidedly think there are cases at the present day where venesection, if practised, would be very beneficial. Because bleeding has been abused ought we to run to the opposite extreme, which I am afraid we are doing, and ignore it altogether?

I will now give a short account of a case where venesection acted, I believe, like magic.

A M.R.C.S., aged twenty-three, short and thin, during the summer of 18—, caught scarlet fever, which was followed during the desquamative stage by dropsy and other symptoms of Bright's disease. When the dropsy had been present about a fortnight, symptoms of uræmia set in, as very severe frontal headache, vomiting, scanty urine, &c. These symptoms were quickly followed by blindness, muscular twitchings (which were localised to the left shoulder for some time), and epileptiform convulsions. After three or four strong convulsive fits the patient was bled to two pints, mustard poultices were applied to the calves of the legs, ice to the head, and a purgative &c. mixture taken. A short time after the bleeding the patient had another convulsive fit, but it was not so strong as the previous ones, and, with the exception of slight muscular twitchings, which lasted a few hours, there were no more bad symptoms. The patient's sight gradually returned, so that in two days it was perfect, and in a week he was well enough to leave his bed. In conclusion, Sir, I may state that the patient was your obedient servant,  
J. J. REYNOLDS, L.R.C.P. Lond., &c.  
Stoke-by-Clare, August 18th, 1882.

**Mr. Chas. Wills.**—The observations of Koch and his assistants on the value and action of disinfectants were published in the "Mittheilungen aus der Kaiserlichen Gesundheitsamt," Berlin, in October, 1881. The book (price 16s.) can be procured through Messrs. Williams and Norgate.

**Mr. Richardson (Appleby Magna).**—Next week.

**Beta.**—If our correspondent will tell us his charges we will give our opinion as to their reasonableness.

**J. H. W.**—The paper is marked for early insertion.

## "DISINFECTION."

To the Editor of THE LANCET.

SIR,—My attention has been drawn to the letter of your correspondent on the above subject, signed Charles Wills, and your remarks in reply to his questions. Having given this matter much consideration, I write to say that I shall be very pleased to give anyone connected with the medical profession an opportunity of trying any experiment they may think desirable in connexion with this important matter in my high pressure steam apparatus if they will only write to the subjoined address and make an appointment.—I am, Sir, yours truly,  
WASHINGTON LYON.

Clifton House, 85, Asylum-road, Peckham, London, S.E.,  
August 19th, 1882.

## ANCIENT SKULLS.

SOME recent explorations in the Trans-Caucasian district have resulted in the discovery of human remains, which Dr. Virchow, of Berlin, considers to afford proofs of the existence of a race of human beings such as the Makrekephall, described by Hippocrates. These large heads would seem to have been produced by the application during infancy of bandages so as to cause the head to grow in a long high form. At a recent meeting of the Berlin Anthropological Society, Dr. Virchow exhibited two of the skulls which had been found as described above.

**Dr. Philip Foster (Leeds).**—Rain water and the very pure water collected on rocky watersheds act continuously on lead. The dissolved oxygen oxidises the lead, and the oxide is distinctly soluble in water. The presence of chlorides or nitrates, particularly of ammonium nitrate, increases this action. On the other hand, the presence of carbonates, sulphates, or phosphates prevents the action from being continuous. Oxide is at first formed, but this is instantly converted into the insoluble carbonate, sulphate, or phosphate of lead, the insoluble compound protecting the lead from further action.

**Mr. J. H. G. Drummond.**—The questions are too wide to be answered here. The better plan would be to obtain prospectuses from some of the nursing institutions, of which there are many in the metropolis. Mr. Hew's Classified Directory (published by Longmans) gives a list of them.

**P. C. S.**—The Animal Vaccine Establishment, Lamb's Conduit-street, W.C.

## "BICYCLE-RIDING."

To the Editor of THE LANCET.

SIR,—In answer to the query of "F.R.C.S." on the above subject, I beg to say that I have had for some four or five years past a large acquaintance among bicyclists of all ages and ranks, and as yet without hearing of a single case of hernia caused by, or even indirectly associated with, bicycle-riding. As a wheelman who has ridden many thousands of miles, I can safely say that there is no action connected with either mounting, riding, or dismounting that will cause the contraction of the abdominal muscles and depression of the diaphragm which are necessary to the production of a hernia. This conclusion I have come to after a careful analysis of the muscular actions attending the propulsion of the machine, and even were I myself ruptured I should have no hesitation as to the continuance of my use of this economical and always ready steed. At the present time I know a man in whom there is so little power of resistance in the abdominal rings that he is nearly always obliged to support himself there when coughing, and yet he tells me that when riding, even fast or up hill, he never has his attention called in the slightest degree to his "weak spot." I should like to point out that I do not wish my opinions to be taken as extending to the tricycle, since the conditions which attend the rider of that machine are widely different in some important points, as I soon found out on the only occasion I have ridden one.—I am, Sir, yours obediently,  
Birmingham, August 20th, 1882. W. G. CRESWELL, L.R.C.P. Ed.

**J. M.**—We think the inquest was justifiable.

**Capt. Lyell and Mr. Smart.**—We do not know M. Regnard's address, and are not aware that the dried blood is to be obtained commercially. Our correspondents had better prepare it for themselves.

**A Reader.**—Physician.

**F.R.C.S. (Liverpool).**—From the last calendar of the Royal College of Surgeons, it appears there are 1210 Fellows of the College, of which number 573 obtained the distinction by examination. The Association will meet next year in Liverpool.

## EXAMINATION MARKS IN SCOTLAND.

To the Editor of THE LANCET.

SIR,—In answer to your Scotch correspondent's query in your last issue, the percentage of marks required for a pass in the degree examinations is 50; from 60 to 75 confers distinction; above 75 high distinction. In the years 1879–1880 no men obtained high, and only three distinction. In 1880–81 three obtained high, and six distinction. In the class-lists the percentage till recently was the same as the above first-class certificates, being those above 75, and second-class those above 60; but in 1881 Dr. Stirling, Professor of Institutes of Medicine, who is an Edinburgh man, assimilated his own class-list to that of his alma mater, and gave second-class certificates to those who made above 50 per cent. But the professional standard still remains unaltered. A couple of other Edinburgh men, who are professors also, this year gave certificates to those who had made above 50 per cent.; hence in anatomy, which includes men of three years, there are a large number of men in the list. As an example of the number of men who obtain certificates, I take the years I have previously mentioned—viz., 1879–80 and 1880–81:—Materia medica, 11; medical jurisprudence, 4; medicine, 3; surgery, 11. 1880–81: materia medica, 7; medical jurisprudence, 18; medicine, 8; surgery, 10. In Edinburgh the percentage for a pass is 40, while above 50 gives honours. I am, Sir, yours sincerely,  
Kent, August 21st, 1882. MEDICUS.

## LAWN TENNIS ARM.

FOR this affection a correspondent recommends the use of pure chaulmugra oil, carefully rubbed into the arm night and morning. This oil, he states, is now generally used by men after their first day's hunting, and also by bicyclists after their first day's long ride, because they find that it entirely prevents any irritation on the skin or stiffness if it is well rubbed in before they retire to bed.

**ERRATUM.**—The presentation of plate at Richmond, Yorks, was made to Mr. Richard Bowes, not John Bowes, as stated last week.

**COMMUNICATIONS** not noticed in our present number will receive attention in our next.

**COMMUNICATIONS, LETTERS, &c.**, have been received from—Professor Gamgee; Professor Atfield; Professor Struthers, Aberdeen; Dr. E. Long Fox, Avening; Mr. Tothill, Colombo; Mr. Willey, Birmingham; Mr. Christy, London; Mr. Richardson, Blackpool; Dr. Steavenson, London; Dr. Neale, London; Mr. W. E. Lloyd, Bristol; Mr. Limont, Newcastle-on-Tyne; Dr. Barton, Market Rasen; Mr. Scott, London; Mr. Jackman; Surgeon-Major Boileau, Oberdale; Dr. Gould, New York; Mr. Warner, Sheffield; Dr. Rockliffe; Herr A. Beck, London; Mr. Martin; Dr. Saundby, Birmingham; Mr. Cresswell, Birmingham; Dr. Sharkey, London; Mr. Reynolds, Stoke-by-Clare; Dr. Bonnejoy, Lausanne; Mr. Jebb, London; Mr. Edmunds, Chesterfield; Mr. Kidd, Dundee; Messrs. Brady and Martin, Newcastle-on-Tyne; Dr. Rayner, Hanwell; Mr. Irving, Grantham; Mr. Hodges, Leicester; Mr. Proctor, Bournemouth; Mr. Shadgett, Gloucester; Dr. Mears, Newcastle-on-Tyne; Mr. Mathews, Old Swindon; Messrs. Fannin and Co., Dublin; Messrs. Coxeter and Son; Mr. Cawston, London; Mr. Marous Beck, London; Messrs. Morrison and Co., London; Mrs. Baines, London; Messrs. ## SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year ..... £1 13 6 | Six Months ..... £0 16 8

TO CHINA AND INDIA ..... One Year, 1 16 10

TO THE COLONIES AND UNITED STATES .. Ditto, 1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 1, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other

Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Canmartin, Paris.

Address  
ON THEGROWTH OF OUR KNOWLEDGE OF THE  
FUNCTION OF SECRETION.DELIVERED ON AUGUST 24TH, 1882, IN THE BIOLOGICAL  
SECTION OF THE  
BRITISH ASSOCIATION.

By ARTHUR GAMGEE, M.D., F.R.S.,

BRACKENBURY PROFESSOR OF PHYSIOLOGY IN OWENS COLLEGE,  
MANCHESTER, PRESIDENT OF THE SECTION.

(Concluded from page 503.)

## THE INVESTIGATIONS AND THEORIES OF BOWMAN.

AT the time when Goodsir was engaged in his investigations and speculations relating to cells, Mr. Bowman was making researches which were to give him a lasting place among the great histologists of the century.

His investigation on the structure of the kidney,<sup>1</sup> which was published in the "Philosophical Transactions" for the year 1842, surpassed in completeness as an anatomical study, no less than by the deep insight into the nature of the function discharged by the organ, any investigation of like kind which had preceded it. It not only led to a more complete knowledge of the structure of the kidney than was possessed of that of any other gland, but to far-seeing generalisations concerning the structure of mucous membranes, and of secreting organs generally, which found expression in a masterly article on mucous membranes, published in the year 1847, in the "Cyclopædia of Anatomy and Physiology."

Time will not permit of my giving a complete analysis of the (to use a German expression) epoch-making research upon the kidney; but let me remind you that it led to a complete understanding of the relations of the Malpighian bodies to the urinary tubules; to a description which, so far as it went, was perfectly accurate of the tubules themselves, though the scheme upon which these tubes are arranged has, since Bowman's time, thanks to the labours of Henle, Ludwig, and Schweigger-Seidel, been proved to be more complicated than he had imagined, and to a knowledge of the distribution of bloodvessels, not only in the kidney of man and other mammalia, but also in that of certain reptiles.

His study of the structure of the tubuli uriniferi had led Mr. Bowman to discover that in these a layer of epithelial cells lies upon a structureless membrane, to which he gave the name of the basement membrane,<sup>2</sup> and which intervenes between the epithelium and the blood capillaries, whence the materials of secretion are primarily derived. His examination of the mucous membranes of the body led Bowman to the conclusion that the relationship so easily observed in the case of the kidney between cells, basement membrane, and bloodvessels, is one which holds true, not only in the case of that organ, but in that of many other epithelial structures.

"In the mucous tissue," said Mr. Bowman,<sup>3</sup> "there are two structures which require to be separately described—viz., the basement membrane and the epithelium. The basement membrane is a simple homogeneous expansion, transparent, colourless, and of extreme tenuity, situated on its parenchymal surface and giving it shape and strength. This serves as a foundation on which the epithelium rests. The epithelium is a pavement composed of nucleated particles adhering together, and of various size, form, and number. The following general observations on these elementary parts will receive illustration as we advance. Neither the one nor the other is peculiar to the mucous tissue in the sense either of being invariably present in it, or of not being found elsewhere. There are certain situations of the mucous system where no basement membrane can be detected, and others from which the epithelium is absent. Both, however, are never absent together. Again, a structure apparently iden-

tical with the basement membrane is met with in numerous textures besides the mucous, and all internal cavities, whether serous, synovial, or vascular, or of anomalous kind (as those of the thymus and thyroid body), are lined by an epithelium."

As a result of his anatomical studies on the kidney, Mr. Bowman was led to frame a theory of renal secretion which, though opposed for a time by a master mind, has, by the progress of research, received complete confirmation, and which was based in no small degree upon the new views of the function of epithelial cells in glands. The Malpighian body, Bowman showed, is the dilated commencement of a convoluted tubule, and, like it, presents a delicate, structureless, basement membrane. Into the Malpighian body projects a tuft of capillary vessels, continuous, on the one hand, with an afferent vessel derived from a branch of the renal artery, on the other, with an efferent vessel of smaller size than the afferent; both afferent and efferent vessels piercing the capsule of the Malpighian body; after leaving the glomerulus, the efferent vessel breaks up into a series of capillaries, which are distributed to the walls of the convoluted tubes. The tuft of bloodvessels projecting into the Malpighian body, Bowman described as being perfectly bare, that is to say, not covered by a basement membrane, or by a layer of epithelium cells. This part of his description has not been confirmed by recent work, the more delicate methods of modern histology allowing of a ready demonstration of a layer of cells of extreme tenuity covering the glomerulus.

The basement membrane of the convoluted tube was described as lined by a nucleated epithelium of a finely granular opaque aspect; the neck of the tube, where it joins the Malpighian capsule, and the contiguous portions of the capsule were described as covered by a layer of cells, differing altogether from the first, being much more transparent, and possessing in certain animals vibratile cilia. In some cases the whole interior of the capsule was lined by epithelium cells of great delicacy and tenuity; in others, these cells could not be traced over more than a third of the capsule. Basing himself upon the altogether exceptional arrangement of the bloodvessels of the glomerulus, Bowman advanced the theory that this is a structure destined to separate from the blood its watery portion. The epithelium of the convoluted tubes, on the other hand, which Bowman pointed out to be "eminently allied to the best marked examples of glandular epithelium," he believed to be concerned in the separation of the characteristic solid matters of the renal secretion.

I shall for the present conclude my remarks upon Mr. Bowman's investigations and theoretical views by stating that, by his investigations of the blood-supply to the kidney of the boa constrictor, he gave the strongest proof which could be derived from anatomical evidence of the correctness of his views, and furnished great part of the knowledge required for the subsequent researches which Nussbaum made on the secretion of the newt's kidney, and which afforded the most conclusive experimental evidence in favour of the theory which Bowman had advanced.

## THE DISCOVERIES OF CARL LUDWIG.

If to Johannes Müller we must ascribe the greatest share of merit as a discoverer of the general affinities relationships, and functions of glands, it appears unquestionable that to Carl Ludwig belongs the credit of having, above all others, brought the light of experimental physiology to bear upon the subject of secretion.

Ludwig is one of the most eminent of the physiologists who have endeavoured, as far as possible, to apply the conceptions derived from a study of physical and chemical processes in general, to the elucidation of the functions of the organism. More than anyone else has he successfully adapted the methods of research of the chemist and of the physicist to the investigation of the problems which lay before him. Above all others he is to be spoken of as the great teacher amongst all of the great teachers of physiology which this century has produced. If we try to find one who, from the fertility of his mind and the influence which he had upon men of ability, affected the progress of his science, in like manner to Ludwig, we revert to the name of Liebig, and when I say that physiology owes as much to Ludwig as chemistry to Liebig, I shall, I feel sure, be doing but scant justice to the great man who at Marburg, at Vienna, and at Leipzig has won for himself the right to be called at once the greatest physiologist and the greatest teacher of physiology of his time.

1. *Ludwig's Discovery of Secreting Nerves*.—It was in the year 1851 that Ludwig first announced to the scientific

<sup>1</sup> W. Bowman, On the Structure and Use of the Malpighian Bodies of the Kidney, with Observations on the Circulation through that Gland, *Philosophical Transactions* for the year 1842, Part I., p. 57.

<sup>2</sup> *Op. cit.* p. 58.

<sup>3</sup> Article Mucous Membrane, in *Todd's Cyclopædia*, p. 436. No. 3079.

world<sup>4</sup> the fact that the secretion of the salivary glands is under the influence of the nervous system. C. G. Mitscherlich, as Ludwig points out, had surmised that the secretion of saliva only occurs as the result of a stimulation of certain nerves—i.e., the nerves of taste and the nerves supplying the muscles of mastication. No attempt had, however, been made, before Ludwig's, to ascertain experimentally whether the stimulation of nerves supplying glands influenced directly their secretion. As a subject of study Ludwig chose the submaxillary gland. He found that on stimulating by a succession of induction shocks the nerve twigs proceeding from the lingual branch of the fifth nerve, which accompany Wharton's duct to the gland, secretion of saliva occurred so long as the excitability of the nerves persisted.

In experiments performed in conjunction with his pupil Rahn, Ludwig found that secretion occurs on direct stimulation of the glandular nerves, even when the circulation has been arrested for a time, as, for instance, when the contractions of the heart are inhibited for some time.

2. *Ludwig's Discovery that Secretion is not a Process directly dependent upon the Arterial Pressure.*—In the paper which I have already quoted, Ludwig published the results of the following experiments. A mercurial gauge was placed in communication with the duct of the submaxillary gland, the height of the mercury in the gauge being recorded (by means of a float to which was attached a writing point) upon the travelling surface of the kymographion, the instrument which Ludwig had contrived for permanently recording the amount and variations of the blood pressure in arteries and veins. At the same time, another gauge placed in communication with the carotid artery, or one of its branches in close proximity to the gland, recorded the height of the blood pressure on the same travelling surface. On stimulating the secretory nerves, Ludwig found that saliva was poured out long after the pressure exerted by it upon the interior of the gland (as measured by the height to which the mercury was raised in the gland-duct manometer) exceeded the pressure of blood in the arteries. Thus, in his first recorded experiment, the mean pressure of blood in the carotid artery amounted to 108.5 millimetres of mercury, whilst during a stimulation of the nerve filaments going to the gland, the pressure in the gland-duct manometer rose to between 190.7 and 196.5 millimetres—i.e., indicated that the pressure exerted by the fluid, secreted under the influence of nerve stimulation, exceeded the arterial pressure by an amount corresponding to a column of mercury about three and a half inches high. It is obvious that the experiment at once and conclusively proved that the secretion of a watery liquid like the saliva may be brought about by a process altogether different from a process of filtration; for in filtration the passage of liquid through the minute pores of the filter necessarily depends upon a difference in pressure on the two sides of the filter, the movement of liquid being from the side of greater to that of lesser pressure.

In this brief sketch I have only time to refer to the most salient of the early discoveries of Ludwig on secretion, and must pass over without comment the first experiments by which he showed the influence exerted by variations in the strength of the stimulus of a secretory nerve upon the amount and chemical composition of the secreted liquid.

3. *Ludwig's Discovery that during Secretion Heat is evolved in Glands.*—Pursuing his researches on the salivary glands, Ludwig some years later,<sup>5</sup> in conjunction with his pupil Spiess, discovered that when a gland is thrown into action by stimulation of its nerves, heat is evolved. In the case of the submaxillary gland, for instance, he found that the saliva which was secreted might have a temperature nearly three degrees Fahr. (1.5° C.) above that of the blood going to the gland. Important as was this result because of the light which it threw upon the source of animal heat, its value as bearing upon the nature of the process of secretion was even greater. From the fact that the saliva is a liquid containing but three or four or five parts of solid matters to one thousand of water, it would scarcely have been surmised, upon a merely physical hypothesis, that its production would have been attended by any considerable evolution of heat. The evolution of heat is indeed one of the strongest proofs we have that the act of secretion is the result of the living

activity of those ultimate units of the glands, the gland cells; but to this I shall revert hereafter.

#### THE RESEARCHES OF SCHIFF, ECKHARDT, AND CLAUDE BERNARD, ON THE SECRETORY NERVES OF THE SALIVARY GLANDS.

The study of the innervation of the salivary glands which had been commenced by Ludwig and Rahn was continued with great success by other observers, and particularly by Claude Bernard and Eckhardt. The first of these observers proved the correctness of Schiff's supposition that the abundant secretion which followed the stimulation of fibres of the fifth cranial nerve was in reality due to the presence of fibres of the chorda tympani mixed with them. It was Eckhardt, however, and afterwards Claude Bernard, who established the remarkable fact that, in the case of the submaxillary gland, and, as has since been shown, of some other glands also, the gland is under the direct control of two orders of nerve fibres. The first are contained in branches of cranial nerves, and in the case of the submaxillary gland are derived from the facial nerve, and, when stimulated, lead to an abundant secretion of watery saliva, relatively rich in saline and poor in organic constituents; the second are contained in the so-called sympathetic nerve trunks distributed to the gland; and these, when stimulated, occasion an exceedingly scanty flow of very concentrated and highly viscid saliva, containing a relatively large quantity of organic constituents, particularly of mucin.

Claude Bernard now pointed out that stimulation of the above-mentioned nerves leads to changes in the circulation of blood through the gland, in addition to the changes in the amount and quality of the fluid secreted by it.

Thus stimulation of the cerebral fibres supplying the chorda tympani was found to produce a great dilatation of the arteries of the gland; so that the amount of blood passing through it was very largely increased, that passing out through the venous trunks of the gland presenting a florid arterial colour instead of the brown venous hue observed when the gland was not secreting. Stimulation of the sympathetic fibres, on the other hand, caused a great contraction of the glandular arteries, consequently a diminution of the flow of blood through the gland and into the veins; the blood presenting under these circumstances an intensely venous hue.

The facts just referred to appeared reconcilable at first with the view that the secretion of saliva, as a result of nerve stimulation, was primarily dependent upon changes in the circulation of blood through the gland; though, upon reflection, the surmise was negatived by some of the facts discovered long before by Ludwig, and particularly by that, already referred to, of glandular secretion following stimulation of glandular nerves, even where the circulation has been stopped, as by cardiac inhibition.

Bernard's experiments had unquestionably established that in addition to nerves which, when stimulated, occasioned the contraction of arteries—the "vaso-motor," or, as we now sometimes call them, the "vaso-constrictor" nerves—there are others which when stimulated occasion, on the contrary, the dilatation of arteries—the so-called "vaso-inhibitory" or "vaso-dilator" nerves. That it was not stimulation of the vaso-dilator nerves, which, by increasing the amount and the pressure of the blood flowing through the capillaries, occasioned the secretion of saliva, was shown by several experiments, but especially by an observation of Kewchell. This observer found that the alkaloid of the deadly nightshade—viz., atropia,—when introduced into the system, exerts such an action, that on stimulating the chorda tympani no secretion of saliva follows; whilst, on the other hand, dilatation of the arteries is produced exactly as under normal circumstances. Other drugs have since been discovered which exert a similar action to that of atropia in paralyzing secretory nerves, whilst some are now known which antagonize the action of atropia, and restore the suspended activity of the secretory nerves. From these studies has unquestionably resulted a knowledge of the conclusion that, although the process of secretion is favorably influenced by the vascular dilatation which follows the state of activity of the vaso-dilator nerves, the actual process of secretion is not due to them, but, so far as it is controlled by the nervous system, is directly under the influence of certain nerves which may be termed secretory.

<sup>4</sup> Ludwig, Neue Versuche über die Bethülfe der Nerven zur Speichelsabsonderung, Henle und Pfeiffer's Zeitschrift, New Series, vol. i. 1851, p. 255.

<sup>5</sup> Ludwig u. Spiess, Sitzungsber. d. Wiener Akad., Mathem. u. Naturwissenschaftl. Classe, vol. xxv. (1868), p. 548.

DISCOVERIES WHICH SHOW THAT SECRETION, THOUGH INFLUENCED BY, IS NOT NECESSARILY DEPENDENT UPON, STIMULATION OF NERVES GOING TO A GLAND.

A knowledge of the facts which I have brought before you hitherto would of itself lead you to suppose that glandular secretion is a process which is in abeyance except under the influence of stimulation of nerves which throw the gland into activity, in the same manner as the quiescent muscle passes into activity normally, only when its motor nerves are stimulated. But this supposition, though it may be in some measure true in the case of certain glands, is not borne out by a study of secreting glands in general—a study which teaches us that whilst the activity of the gland cells may be, and often is, remarkably under the control of the nervous system, it is by no means necessarily dependent upon it. The activity of the gland depends upon the activity of its individual units, the gland cells; and these units may discharge their function so long as they continue to live and are supplied with the nutriment, mineral, organic, and gaseous, which they require.

Leaving aside, at least for the present, any reference to the arguments which may be derived by analogy from a study of cell life in general, I would call your attention to the physiological facts which prove the truth of the proposition just enunciated. The first of these facts was discovered by Claude Bernard—to wit, that when all the nerves supplying the salivary glands are divided, there is at first a temporary cessation of secretion, soon followed, however, by an abundant flow of very watery, so-called paralytic saliva.

This result is fully confirmed by similar observations made in the case of other secreting organs, and which establish very fully the greater or less independence of the secreting elements from the control of the nervous system; though unquestionably, in a normal state of the organism of higher animals, the nervous system is continually intervening, both directly by its influence on gland cells, and indirectly by the changes which it produces in the circulation, so as to control the operations of gland cells, and especially to bring them into relation with, and subordinate them to, the work of complex processes of the organism.

What the exact relations of nerve fibres to gland cells may be is yet a matter involved in great doubt. The discovery made by Pflüger of the terminations of nerve fibres in the secreting cells of the salivary glands has not been confirmed by any observer in any vertebrate. Kupfer has, however, unquestionably done so in the case of *Blatta orientalis*, and although as yet objective proof is wanting, we cannot entertain any reasonable doubts that a connexion between the ultimate fibrillæ of nerves and secreting cells actually exists.

#### THE IMMEDIATE SOURCE OF THE NUTRIMENT CONSUMED BY THE GLAND CELL.

In the original scheme of a secreting gland, developed first of all by Bowman, then adopted by Goodsir, Carpenter,<sup>6</sup> and many other writers, the essential structural elements taken into account were the following:—(1) Epithelial cells lining the secreting cavity of the gland; (2) subepithelial tissue, usually presenting superficially the form of a basement membrane, upon which the cells were placed; and (3) a capillary network in closer relation to the basement membrane, or more superficial part of the subepithelial tissue. In harmony with this scheme, the glandular elements were always spoken of as drawing their supply from the blood in the capillaries. The one element which was wanting in that scheme, and which we are able to fit into it, thanks again to the labours of the great physiologist of Leipzig, is the relation of so-called lymph spaces to the other elements. As was first shown by the researches of Ludwig and his school, amongst the modes of origin of the peripheral lymphatics, the most numerous are to be found in connective tissue, and nowhere more abundantly than in the connective tissue of glands, which is everywhere interpenetrated by irregular spaces containing lymph, whence spring the minutest lymphatics. If we consider, then, the immediate environment of the secreting cell, we find that in close proximity to it is the lymph, which is a transudation from the blood, and upon which the gland cells are directly dependent for all the matters which they require. For a certain time, then, the gland cell will be independent of the supply of blood—that is so long as the lymph surrounding it contains a sufficient quantity of essential matters, of which oxygen is one of the

chief, to support its life, or until it becomes so charged with waste products derived from cell-life—e.g.,  $\text{CO}_2$ , as to interfere with the functions of the latter. It certainly appears that, at least in the majority of cases, it is the secreting cell which modifies, in the first instance, the composition of the lymph which bathes the tissues in proximity to it, rather than the composition of the lymph which modifies the activity of the gland cell. There are some cases, nevertheless, in which it would appear that the presence of certain constituents in the lymph is the direct cause of the activity or increased activity of the cells.

#### SECRETING CELLS PRESENT DIFFERENT APPEARANCES, CORRESPONDING TO DIFFERENT STATES OF FUNCTIONAL ACTIVITY.—THE RESEARCHES OF HEIDENHAIN.

Amongst the physiologists of Europe who have most enriched science by their researches during the last thirty years is unquestionably Professor Heidenhain of Breslau, who has exhibited his mastery of the physical side of physiology by his classical research on the relations between the heat evolved in and the work done by muscle, and as a biologist able to use in the best manner all the resources of modern histology in the elucidation of bodily function, by the researches to which I wish now to direct your attention.

The glands imbedded in, or the ducts of which open upon the surface of the mucous membrane of, the alimentary canal, for the most part are characterised by periods of more or less complete cessation of activity, as judged by the diminution, or absolute cessation, of the secretion which they prepare. This is true of the salivary glands and of the liver, but particularly true of the gastric glands and the pancreas.

Certain of these glands—i.e., the salivary glands in some animals, and the stomach and pancreas in all in which they exist—have the task of preparing juices which contain certain so-called unformed or unorganised ferments or “enzymes,” upon which the properties of the secretions in great measure depend. Heidenhain in a long series of investigations, which have been taken part in by certain other scientific men, as by Ebstein and Grützner, by Kühne and Lea, and particularly by Mr. Langley of Trinity College, Cambridge, has shown that the secreting cells of a particular gland, as for instance of the submaxillary gland, of the gastric glands, and of the pancreas, exhibit differences in size, differences in the form and appearance of the nucleus, and differences in the cell contents, corresponding to varied states of functional activity.

Time will not permit my mentioning in detail the results of these observations, from which, however, certain general conclusions appear derivable. Thus, a gland cell at rest is usually larger than a similar cell which has been engaged in the process of secretion; from its behaviour to reagents, it usually appears to contain within itself an abundant store of the body or bodies which are chiefly characteristic of the secretion, or closely related antecedents of these, and the amount of undifferentiated protoplasm surrounding the nucleus appears to be at a minimum. On the other hand, the gland cells, which have been secreting for a greater or less period, often, though not invariably, present a diminution in their size, a diminution in the amount of the characteristic bodies previously referred to, and an increase in the protoplasmic constituents of the cell. All facts, histological as well as physiological, seem to point to the following conclusion: that during rest, the cell forms, at the expense of, or as the product of the differentiation of, the cell protoplasm, the bodies characteristic of the secretion; that whilst secretion is going on these leave the gland cell; and that, at the same time, the protoplasmic constituents of the latter increase at the expense of the lymph, to be converted secondarily, either at a later period in that particular act of secretion, or in the succeeding period of inactivity, into specific constituents. The researches of Heidenhain have been conducted upon the glands after these had undergone processes of hardening and staining, the appearances observed indicating changes which though not identical with, at least corresponded to various conditions of the gland. Kühne and Lea and Langley have, however, studied glands in a living condition, and though the appearances were not identical with those observed by Heidenhain, they entirely confirm these.

I have not time to do more than refer to the fact that in some at least, though probably in all of the cells of glands which produce secretions containing ferments, there are formed at first bodies to which the generic term of

<sup>6</sup> Carpenter, in his admirable article on Secretion in Todd's Cyclo-pædia

"zymogens" may be applied — i. e., *ferment generators*, from which a ferment is afterwards set free.

In connexion with this part of my subject I may refer to the view, which was at one time held by some, that in secreting glands the gland cell having produced the matter of the secretion was thrown off, discharging its contents into the secretion. This process, when it does occur, must be looked upon as exceptional, and as it were accidental.

Amongst the most striking examples of the success with which physiological experiment and subsequent histological research have been pursued in combination so as to throw light upon the functions of particular cells, I may refer first to the observations of Heidenhain, secondly to those of Nussbaum on the excretion of colouring matters, artificially introduced into the blood, by the secreting epithelial cells of the renal tubules. I have previously referred to the theory of Bowman, according to which the watery and saline constituents of the renal secretion were supposed to be separated by the so-called "glomeruli," whilst the organic solids of the secretion were supposed to be separated by the epithelium lining the convoluted tubes.

To this theory was opposed that of Ludwig, according to which the whole of the constituents, watery, saline, and organic, were supposed to be poured out of the vessels of the glomerulus, the amount of water, however, being far in excess of that contained in the liquids when it reaches the pelvis of the kidney. Ludwig supposed that as the secretion passed over the surface of the epithelium lining the complex tubules, processes of diffusion occurred between it, on the one hand, and the lymph bathing the tissues lying outside of the basement membrane of the tubules on the other, the direction of the current of water being from without inwards. The anatomical evidence adduced by Bowman was of itself well-nigh sufficient to prove the accuracy of his views, which have however been placed beyond all dispute by the following observations: Heidenhain introduced into the blood a solution of sulphindigotate of sodium, usually some time after having divided the spinal cord in the cervical region. On killing the animal some time afterwards and subjecting the kidney to careful examination, it was found that the colouring matter had been accumulated by the epithelium of the convoluted tubules from the lymph bathing the tissues, and which contained so little colouring matter as to appear colourless. If a sufficient time had elapsed after the injection, the colouring matter was found in the form of granules or minute crystals lying on the inner side of the cell in the lumen of the tubules.

Bowman, as I have already mentioned, had in the case of the boa constrictor studied in detail the blood-supply to the organ, which, as Jacobson had shown, differs in fishes, birds, and reptiles, from the mode of arrangement prevailing in mammals. Bowman had shown that in the boa the glomeruli derived their blood exclusively from the renal artery, and the convoluted tubes exclusively from the common iliac vein. Nussbaum gave absolute completeness to the proof of Bowman's theory by the following remarkable experiment. Experimenting on the newt, in which the blood-supply of the kidney is similar to that of the boa, he found that, when he tied the renal artery, he arrested almost entirely the secretion of water in the kidney, but that the excretion of urea and other solid matters, and amongst others of the colouring matter already used by Heidenhain—viz., indigo, carmine—continued. Ligation of the renal branches of the common iliac vein stopped the secretion of organic solids without impeding that of water.

#### THE MOST RECENT THEORIES ADVANCED IN EXPLANATION OF THE PHENOMENA OF GLANDULAR SECRETION.

Having brought before you the most salient facts with which we are acquainted which appear to throw the most light upon the general physiology of glandular secretion, I wish to speak of the theoretical views which have been advanced in explanation of a large number of the facts.

In the first place, I have to confess that our ignorance is absolute as to the cause of the specific endowment of different secreting cells, in virtue of which they produce new bodies at the expense of certain of the materials supplied to them by the lymph, or separate particular constituents from the lymph, to the exclusion of others which are equally abundant in the liquid. We express the full measure of our ignorance when we state that the difference in function of different gland cells is due to differences in endowment of the protoplasm of the cell, which in no case is explained by any objective characters of the cell.

The phenomena of the secretion of water, which forms so large a part of every secretion, have given rise, however, to numerous speculations. The primitive view that the glands are organs in which is strained off from the blood water holding certain substances in solution is held, in a modified manner, by some even now, and appears, indeed, at first sight, to be borne out by certain facts. Thus within wide limits the amount of water secreted by the kidney depends upon the pressure of blood in the glomeruli. Any circumstances which will lead to an increase of pressure in these vessels (as increase of blood-pressure generally, division of renal nerves, division of the splanchnics, especially when combined with stimulation of the spinal cord), by dilating the branches of the renal artery, will lead to this result. At first this would seem to show that the process of separation of water, in the kidney at least, is but a process of filtration, though a remembrance of the famous experiment of Ludwig, referred to at an earlier period, on the relation between the pressure of secretion of saliva and that of the blood in the arteries, would impose caution in drawing the conclusion. What are the facts, then, relating to the blood pressure in vessels in other organs of the body, and the transudation of liquid from them?

If an increased arterial pressure led *ipso facto* to an increased transudation through the capillary walls, it would follow that the amount of lymph and the pressure of the lymph stream would rise with the rise of the arterial pressure, but direct experiments on this matter have led to an opposite conclusion. The experiments of Paschutin and Emminghaus, carried out under Ludwig's direction, have shown that when the arterial pressure in the extremities is increased, there is no corresponding increase in the lymph produced. Again, when the chorda tympani is stimulated in an animal into whose blood atropia has been introduced, the vascular dilatation which is produced, and which is then unaccompanied by secretion, does not lead to an increased production of lymph, which would make itself evident by the gland becoming oedematous. How, then, are we to account for the flow of water through a gland? By ascribing it to an influence which is exerted by the gland cell, in the first place, upon the liquid which environs it—viz., the lymph. And accordingly, even in the case of the glomeruli of the kidney, we conclude that the water is separated as a direct result of the activity of the layer of transparent epithelium cells which cover them. Hering has advanced a strictly physical theory, which would account for the mode in which certain cells exert this influence, by supposing that there is produced within them bodies which, like mucin, have a great affinity for water, and which then pass into the secretion; and which therefore lead to a current of water passing through the cell; but the theory is one which cannot be admitted, because, as Heidenhain points out, the passage of water through a gland occurs in cases where there is no constituent in the cells at all resembling mucin in its affinities or behaviour towards water. I feel inclined to say that the speculations, necessarily indefinite though they are, of Heidenhain afford the best explanation of the phenomena. Heidenhain starts from the fundamental fact that during secretion only as much water passes out of the bloodvessels of the gland as appears in its secretion, seeing that, however long the process of secretion may continue, the gland never becomes oedematous, nor does the current of lymph from it increase.

The volume of liquid filtered through the blood capillaries adjusts itself exactly to the volume of liquid separated by the cells. This equality in the amount of liquid secreted and filtered appears only explicable on the supposition that the act of secretion is the cause of the current of water—in other words, that the water which the cells lose in the formation of the secretion generates changes in them which can only be compensated for by an abstraction of water from the immediate environment.

Within certain limits, Heidenhain continues, we may form purely physical conceptions of the process. We may conceive, for instance, the whole protoplasm of the cell to have a certain affinity for water. The cells at their contact with the basement membrane may be supposed to be able to abstract water from it; the loss which the membrane sustains will be made up by the lymph, and this again will influence the blood in the capillaries.

The passage of water into the cells will go on until a period of equilibrium is attained; but at that time the current of water from the capillaries through the lymph to the cells will cease. We may conceive further, reasons Heidenhain,

that the passage of water out of the cell is hindered by such obstacles to the process of filtration as are represented by resistance opposed to it by the superficial border layer of protoplasm. If we now conceive that, for example, as a result of nerve stimulation, the gland cells pour out water, the condition of equilibrium which existed between cell, basement membrane, lymph, and capillary will be disturbed, and a current of liquid set in from the last to the first, and continue as long as the activity of the cells continues.

It is not difficult, moreover, Heidenhain remarks, to form physical conceptions of the processes whereby water may be separated from the cell itself. It is conceivable, for instance, that the protoplasm of the cell may contract after the manner which occurs in many infusoria, and which in them leads to the accumulation of water in droplets, forming vacuoles, except that in the case of the secreting cells the water is poured out on the outside, and not on the inside, of the cells. Or, again, it is possible that on the gland cell passing into the condition of activity an increased production of  $\text{CO}_2$  may occur, leading to an increased diffusion of water outwards.

So far, I have quoted Professor Heidenhain, for the most part, in his own words. Let me add, however, that the two hypotheses which he advances as possible explanations of the mechanism of secretion of water by the cell rest upon the most probable grounds, as upon the presence of the intracellular protoplasmic network which has been so beautifully demonstrated by recent researches, and especially by those of Professor Klein; or, again, upon the fact, proved by the analyses of Professor Pflüger of the gases of the saliva, that there is during secretion great production of  $\text{CO}_2$ , as shown by the amount of this gas in the saliva being much greater than in the blood, and upon the fact of the remarkable diffusibility of acid solutions.

Reasoning upon a large number of facts, which I have not time to refer to, Professor Heidenhain has come to the conclusion that, quite apart from the nerves which control the vascular supply to a gland, there exist two distinct sets of nerve-fibres in relation to the glandular elements. The first of these, which he terms "secretory," when stimulated lead to the secretion of water and saline constituents; the second, which he terms "trophic," influence the transformations of the protoplasm of the cell, and thus affect the organic constituents of the secretion.

I do not wish to pronounce a definite opinion concerning this hypothesis, but would remark that the nomenclature proposed by Heidenhain appears to me to be an unfortunate one, especially because it attaches a new meaning to a word which had previously been used by physiologists in a different sense. I refer to the adjective *trophic*, which has always implied "governing nutrition." It appears to me almost inconceivable that if there exist two sets of secretory nerves, the action of each should not profoundly affect the nutrition of the cell protoplasm, though, of course, it is conceivable that they should do so in very different manners.

#### GENERAL CONCLUSIONS.

The complicated studies, of which I have attempted to give you a brief sketch, have led to our forming certain clear general conceptions in reference to the process of secretion. They have brought into greater prominence the dignity, if I may use the expression, of the individual cell. The process of secretion appears as the result of the combined work of a large number of these units. Each, after the manner of an independent organism, uses oxygen, forms  $\text{CO}_2$ , evolves heat, and derives its nutriment from the medium in which it lives, and performs chemical operations of which the results only are imperfectly known to us, and which depend upon peculiar endowments of the cell protoplasm, of which the causes are hidden from us. So long as the protoplasm is living, the gland cell retains its power of discharging its functions, and in many cases does so, so long as the intercellular liquid furnishes it with the materials required. In some cases, however, the gland cells are specially sensitive to a variation in the composition of the nutrient liquid, certain constituents of which appear to stimulate the protoplasm to increased activity. In the higher animals the cells, particularly in certain glands, are in relation to nerves which, when stimulated, affect in a remarkable manner the transformations of their protoplasm, leading to an increased consumption of oxygen, an increased production of carbonic acid, an increased evolution of heat, and an increased production of those matters which the cell eliminates and which constitute its secretion.

This historical survey of the growth of our knowledge of the process of secretion exhibits the characteristic features of biological advancement. Comparative anatomy has been the foundation of, observation of facts and physical experiment, the road to physiological research. At various stages the value of hypotheses has been well illustrated, and whenever they have had to make way for the broader and truer interpretations suggested by the accumulation of facts and greater precision of observation, it has been demonstrated that the process of observation is not one of simple sight, but of complex ratiocination.

#### ABSTRACT OF A

#### Lecture

ON

### OIL OF EUCALYPTUS IN MIDWIFERY PRACTICE.

*Delivered at the Glasgow Maternity Hospital, July 3rd, 1882,*

By SAMUEL SLOAN, M.D., F.F.P.S.G.,

OBSTETRIC PHYSICIAN AND LECTURER ON CLINICAL OBSTETRICS AT THE HOSPITAL.

[AFTER some remarks on the nature of "puerperal fever," the symptoms of a typical case of acute puerperal septicæmia were given, and also of a case of puerperal pyæmia; and the relationship of these diseases to surgical fever was shown. These being diseases associated with putrefaction, the importance of thorough cleanliness during labour and throughout the puerperal condition was insisted upon. The following were noticed as amongst the predisposing causes of septicæmic poisoning: 1. The readiness with which the lochial discharge decomposes. 2. The natural condition of the generative tract after parturition. 3. The various lacerations—perineal, vaginal, and cervical—either at the os or in the cavity. 4. The intense prostration of the nervous system, so marked in many of the single women in maternity hospital practice—so great as sometimes to amount to mental collapse: this condition vastly increasing the tendency to absorption of the discharges. The dangers of infection were also dwelt on.]

To wait for the appearance of symptoms of mischief is sometimes a fatal mistake, as the system may be overpowered by the disease before there is any warning of danger. It is therefore of the utmost importance in the employment of antiseptics in midwifery practice to use them from the very first, since the blood may be poisoned within twenty-four hours after the completion of labour. The advantage of retaining for several days after parturition an efficient contraction of the uterus is obvious, and for this purpose I give, as a matter of routine, a mixture like the following, which I find also very serviceable as a preventive of after-pains:—Solution of muriate of morphia, one drachm and a half; tincture of nux vomica, half a drachm; liquid extract of ergot, two drachms; tincture of orange, three drachms; water to two ounces. One drachm in a little water every four or six hours. That injections of water mixed either with carbolic acid or Condy's fluid are valuable cannot be denied; that in cases of excessively fetid lochia, with general febrile disturbance, they may act like a charm I have often found. These latter are cases, however, in which the blood seems to be charged with only the chemical products of decomposition; and it must be admitted that in cases of genuine septicæmia the employment of injections is often of no avail. Of course, if used from the first day, they will go far towards preventing or diminishing septic mischief. They are, however, irksome to the patient, whilst in the hands of an unskilful nurse they may be a positive danger.

That a midwifery case cannot be conducted throughout on absolutely antiseptic principles will be readily admitted by those of you who are familiar with antisepticism as carried out in surgical practice. We should, however, endeavour to come as near to this standard as is possible to us as obstetricians. That vaginal or even uterine injections of

antiseptic fluid every few hours come near to complete antisepticism is absurd. In order to act efficiently on the lochial discharge we ought to attack it with the antiseptic as it pours from the os uteri, and to keep up this action continuously. What antiseptic will best suit for this purpose? Carbolic acid, which has proved so great a gain to the surgeon and in a diminished degree to the obstetrician, has the following objections:—1st. In the quantities required it would be poisonous. 2nd. It would cause severe irritation, and thus prevent the healing of lacerations. 3rd. It would coagulate the lochial discharge, causing its retention even within the uterus. 4th. To many patients it has a decidedly sickening odour.

Now, when at the meeting of the Clinical Society of London on the 13th of May, 1881, Mr. Lister recommended oil of eucalyptus as a substitute for carbolic acid where the latter was inadmissible, it occurred to me that this substitute might be more extensively employed in obstetric practice than had been considered safe with carbolic acid. Since then I have put it to the test, and its advantages I have found to be the following:—1st. It is non-poisonous. 2nd. In the quantity and strength required it is unirritating. 3rd. It does not coagulate the lochia, which, by separating the lips of the vulva, can be seen to flow out in a liquid stream. 4th. Its odour is, with rare exceptions, a pleasant one. 5th. It seems to act as a uterine stimulant, causing and assisting to maintain uterine contraction. Formed into a pessary of a suitable shape and size it is easily applied to the neighbourhood of the os, and retained there. To secure this, the pessary must be broad and short, must melt slowly but completely, and must contain a large percentage of the antiseptic oil. These requisites I have found the following formula to supply:—Oil of eucalyptus, six drachms; white wax, four drachms; cocoa butter, four drachms; mix and divide into twelve pessaries. One of these must be applied night and morning immediately after the usual sponging, and, though the napkins are frequently changed, the odour will be quite perceptible on the one removed prior to the next sponging twelve hours later. In cases of miscarriage, or when the lochia has diminished materially in quantity—say, six days after confinement—I have found the above strength produce irritation, and the following will then be found preferable:—Oil of eucalyptus, four drachms; white wax, 160 gr.; cocoa butter, four drachms; divide this mixture into twelve pessaries, and label them No. 2. These also may be used at first night and morning, and afterwards at night only. I show you these pessaries; they are made by first melting together the wax and cocoa butter in a vessel resting in hot water; the oil of eucalyptus is then mixed with this, and the fluid poured into the ordinary two-drachm pessary mould, each cavity being somewhat more than half filled. I have never been able to satisfy myself that the eucalyptus was absorbed into the system to any material extent. This is probable, however, and, in one case, seemed to be proved. This was a case of severely ruptured perineum, which was stitched and united throughout. The pessaries had been continued for sixteen days, when an erythematous rash appeared over the whole body, disappearing immediately on the cessation of the eucalyptic treatment. Though uncertain as to the fact of a material absorption of the oil into the system, I am persuaded that the oil does not remain at the os, but freely passes into the cavity of the uterus. For it is admitted that the uterus for several days after labour is naturally in an alternate state of contraction and relaxation, and whilst during contraction it will empty itself, during relaxation again whatever is lying at the os or upper part of the vagina will be sucked into the vacuum produced. The eucalyptus will therefore find its way quite into the uterine cavity. When I said that, with rare exceptions, the odour is agreeable, I referred to a decomposition of the eucalyptus oil which sometimes takes place, giving the napkin a semi-fetid odour. That this does not arise from a change in the lochia I have proved by simply omitting the next pessary when due; I then found that the lochia was absolutely sweet.

When I began a year ago to use this antiseptic in hospital practice, I ordered the pessaries to be used only for those patients who, from the nature of their labour or other cause, were likely to give trouble; and to those patients whose lochia had become offensive or whose recoveries were interrupted. In the case of the former the pessaries were begun immediately after labour; in the latter on the appearance of bad symptoms. In the former the result was invariably

satisfactory; in the latter the treatment was a recognised aid to other measures. It was soon noticed, however, that the cases in which the labour was easy and natural gave afterwards considerable anxiety, usually from unrecognised mental distress, perhaps increased by the receipt of unwelcome news. I soon therefore saw the necessity for beginning the antiseptic pessaries immediately after labour in the case of all the patients. The consequence was that whereas offensive lochial discharge had been no rarity—and when once this appeared in one patient it rapidly spread to others—fetid lochia was almost entirely banished; the only case of undoubtedly putrid lochia having arisen from extensive superficial gangrene of the vagina, after a severe labour completed by the forceps. This woman, moreover, made a rapid and complete recovery. In some of the cases an offensive odour was suspected, but this had generally vanished when the next napkin was removed; or, if it persisted, was found to have arisen from the fact that the pessaries had been for a considerable time in the hospital, having thus lost part of their volatile oil. They ought therefore to be made as far as possible just as they are required, since they will change after a few days. During this period one of the patients had severe ascites, from which she died. There had been a history of disease, the exact nature of which could not be ascertained, but hepatic disease was supposed to be the cause of the ascites. About seventy ounces of fluid were removed by tapping. This fluid was absolutely sweet when removed, and it remained so for days after, making it exceedingly probable that there was no septic element in the peritoneal condition.

In private practice, where the class of patients is of a more hopeful nature, I have restricted the use of the pessaries to the cases requiring special treatment from the beginning of the puerperal state. Amongst these were the following:—A case of inversion which I was not called to till several hours after its occurrence; a case of premature labour following acute bronchitis in which the patient was almost in a state of collapse; a case of subacute phthisis; cases requiring operative treatment and with dangerous complications. These cases all did extremely well. In only one of them—the case of phthisis—was there at any time an offensive discharge, and this was in the second week, and forty-eight hours after the last pessary had been introduced. I should mention that it is now the practice at this hospital, as a special precaution, to use carbolic vaginal injections night and morning just before the introduction of the medicated pessary. In my private practice, however, the usual night and morning carbolic sponging alone preceded the use of the eucalyptus.

Regarding the use of eucalyptus as a curative in pyæmia, I have fortunately only one case to bring before you. In relating it I shall confine myself to the main points of the case.

Mary Anne M— was admitted and delivered on November 22nd, 1881. Her labour was easy and normal. Beyond a "scared" look, and the fact that this was her third (?) illegitimate child, the case presented nothing unusual. The temperature rose, however, on the fourth day, and continued high. For some time there was nothing to account for the fever, there being no abdominal distension or tenderness till later on, and the discharge remaining sweet throughout the entire illness. No pessaries were used till the fever had set in. The patient steadily becoming worse, was, at an early stage of her illness, removed to another ward, which was set apart for herself and her nurse. It was not till the third week that the true nature of the disease was apparent. At this time several parts of the limbs became swollen, whilst later on a large fluctuating swelling appeared on the back of the chest. The treatment consisted at first mainly of large doses of quinine with aconite and a liberal amount of stimulants. Later on eucalyptus was given internally by the mouth and by the rectum. By the twentieth day it was perfectly evident that the patient was sinking, and that a few hours would see the end. Determined not to leave anything undone, I now ordered hypodermic injections every hour of a mixture composed of oil of eucalyptus, five minims, and olive oil, twenty minims. I had found that one part of eucalyptus to two parts of olive oil could be borne without irritation by a granulating perineum, and I thought one to four a safe strength to start with for hypodermic injection. This producing little or no irritation, the quantity was gradually increased to eight minims of eucalyptus to sixteen of olive oil. It was soon evident that the patient was

rallying; but as she improved, the irritation produced by the injections became so great that the resulting swellings could not be distinguished from those arising from the disease. The injections were now diminished in frequency, and finally, on the fourth day, abandoned. Soon the patient began again steadily to lose ground, rallying again on the resumption of the hypodermic injections. For a considerable time she seemed to hang between life and death, but under the generous care of the matron and the house-surgeon she gradually improved, leaving at last for the Town's Hospital with abscess of the left knee only, all the other swellings having slowly disappeared. There the knee was opened, and the case made most satisfactory progress. The woman called on me a few weeks ago. Her general health was then excellent, and beyond a slight limp she bore no traces of her illness.

From one case it would be unwise to draw positive conclusions as to the benefit of the eucalyptus used hypodermically as a cure for pyæmia, but I think I am justified in recommending that, under similar circumstances, it should be tried.

## A CASE OF MEGRIM, WITH PARALYSIS OF THE THIRD NERVE.

By R. SAUNDBY, M.D. EDIN., M.R.C.P. LOND.,  
ASSISTANT-PHYSICIAN TO THE GENERAL HOSPITAL, BIRMINGHAM.

THE following case is, I believe, in many respects quite unique. Megrim accompanied by various motor disturbances has been recorded by Abercrombie and others; but these, while supporting the view that the pathological condition about to be described is rightly attributed to this peculiar class of neurosis, differ from it in many important particulars. As the ocular symptoms were most interesting, I sent the case several times to Mr. Eales, and his notes have enabled me to make it far more complete than I could have done without his assistance, and I take this opportunity of thanking him for the time and care he has so kindly given to its investigation.

Maria S—, aged nineteen, single, of no occupation, was admitted as an out-patient to the General Hospital on Jan. 15th, 1880, complaining of biliousness and drooping of the left eyelid. She stated that she had been ill five days, her illness having begun with sickness and pain in the left eye; the eyelid began to droop on Tuesday. She cannot account in any way for this attack. Her previous general health had been good; she had scarlatina when four years old, but has had no other illness except attacks similar to the present one, which have come at intervals of six or nine months ever since she was twelve years old. On each occasion the symptoms have been the same, sickness, pain over the left eye, and ptosis. She is usually very drowsy during these attacks. She was a well-developed girl, of fair complexion, with no abnormal symptoms or signs in the thorax. Her tongue was clean, but she said it had been very dirty. The vomiting had stopped that day. Her bowels were regular. Menstruation was regular and normal. Urine normal. She cannot sleep at present on account of the pain over the left eye. She was giddy yesterday; the pain is better to-day. Hearing and taste normal. Has never had any fits.

*Examination of eyes.*—Right eye:  $V = \frac{1}{2}$ . On ophthalmoscopic examination, a suspicious-looking hazy band was seen running across an artery and vein above the disc; the inner margin of the disc was not clearly defined. The vessels, especially the arteries, were large. —Left eye: Ptosis; complete paralysis of upper, lower, and internal recti. Pupil dilated more than the other, but not completely. Incomplete paralysis of sphincter and dilator muscles of iris. Paralysis of accommodation. On ophthalmoscopic examination the outer side of the disc was not very distinct.  $V = \frac{1}{2}$  unaided;  $= \frac{1}{2}$  with perforated disc. Astigmatic: vision not improved by  $-70$  or  $+70$ . Her father and mother are both living. Father healthy; mother not well, but no definite disease. Has two brothers and one sister, all in good health; one brother died at the age of five of scarlatina. The patient was ordered a mixture containing rhubarb and soda, and two days later reappeared, feeling much better; the ptosis was less marked, there was no pain,

and she could eat well. Eyes, under atropine: Ptosis perceptibly less, but still present.

*Movements of eyes.*—Upwards, nil; inwards, nearly complete; downwards, good; outwards, good. In convergence inward movement was good, but still some slight insufficiency. Ophthalmoscopic appearances: Fundus normal; disc oval.  $V = \frac{1}{2}$  with perforated disc.

Jan. 21st: Feels well; ptosis about the same. She was ordered a tonic mixture containing mineral acid and strychnia. Eyes same as last note. There was no change noted till the following date.

Feb. 6th: With back to light both pupils the same size. Facing light, right pupil contracts more than left. Left pupil, moreover, is oval from above downwards; it contracts to light and on convergence, but more slowly and less completely than right. All the movements of the eyeball are perfect except upwards, the eye not passing above the horizontal plane. No ptosis now.—26th: Ptosis has disappeared almost entirely, but is evident at times. She has occasional headache, sickness, and giddiness, with pain over the left eye.

March 5th: As the ptosis did not disappear entirely, the following mixture was prescribed: Ten grains of iodide of potassium, five grains of bromide of potassium, one ounce of the decoction of sarsaparilla, to be taken three times a day.

April 12th: She had had a bad attack of pain and sickness again three days previously.

I had lost sight of her altogether for two years, when, on April 25th of the present year, she returned, with all her old symptoms fully developed. There was very marked ptosis of the left eyelid, and paralysis of all the muscles supplied by the third nerve; the pupil was dilated. The attack began a month ago with headache (pain in the left temple), sickness, furred tongue, and constipation, which continued for three days, when the eye began to droop. The pain and sickness have gone off, the tongue is clean, and the bowels are acting naturally. The patient says she has had "bilious attacks," since she was here, but has not had any drooping of the eyelid; with the exception of the "bilious attacks," which have been as frequent as every month, her health has been fairly good.

*Examination of eyes.*—Left eye: complete paralysis of all branches of the third nerve; ptosis; upper, lower, and inner recti, and also lower oblique, paralysed; external rectus and superior oblique intact; eye looks partially down and out by means of superior oblique, and rotates round antero-posterior axis at the same time. This rotatory movement ceases when the eye no longer looks downwards and outwards. The left pupil does not dilate more than the right in dull light, but does not contract, or only very slightly, on sudden exposure to full light. Paralysis of accommodation also.  $V = \frac{1}{2}$  only. Ophthalmoscopic examination shows inner side of disc indistinct.

May 10th: Eye better; slight recovery of power in the rectus internus and levator palpebrarum. Upper and lower recti still quite paralysed; also paralysis of pupil and accommodation.—23rd: Ptosis almost gone; upper rectus quite paralysed; lower rectus beginning to recover; inner rectus considerably better; pupil still a little larger than the other.

July 7th: Paralysis of superior rectus complete. Movements downwards and inwards good, but not so great in the other eye; slight ptosis still. Right pupil larger than left, but in bright light right pupil smaller than left; left pupil contracts slightly in convergence. Patient sees double only when she looks upwards.

The main points about this case are the attacks of megrim, coming on at intervals, accompanied by paralysis of the muscles supplied by the left third nerve; some atony of the fibres supplied by the sympathetic, as seen by the failure of the pupil to dilate in a dim light in spite of the paralysis of the sphincter; and, in addition, the permanence of (1) complete paralysis of the superior rectus, (2) a slight degree of ptosis, (3) more or less amblyopia of the eye affected. I think the description of the attacks, the history of their recurrence over so long a period as seven years without any particular affection of the general health, and the absence of any reasonable suspicion of syphilis, together with the failure of iodide of potassium to modify the symptoms, justify the conclusion I have formed, in no hasty manner, that this is a case of true megrim associated with paralysis of the third nerve. Dr. Wilks<sup>1</sup> mentions megrim among the causes of paralysis of the third nerve, though he does not

<sup>1</sup> Diseases of the Nervous System, p. 436.

include the symptom in his description of this form of headache, and Horner<sup>2</sup> has specially described a form of ptosis in megrim which he attributes to paralysis of the non-striped muscular fibres of Müller, which are distributed in the orbicularis palpebrarum, and are supplied by the sympathetic. Eulenburg<sup>3</sup> and Rosenthal<sup>4</sup> mention the symptom, but merely refer to Horner's paper. That such a condition is rare is proved by the absence of all mention of it in Dr. Living's<sup>5</sup> well-known monograph on megrim, and in Galewowski's<sup>6</sup> more recent paper on the ophthalmic phenomena of megrim.

On the other hand, it is well known that megrim does give rise to a great variety of peculiar nervous phenomena, among which are temporary, partial, or complete blindness, hemiopia, luminous spectra, numbness and tingling of the fingers, mouth, lips, and tongue; cramps, transient hemiplegia, loss of taste, smell, and hearing, loss of speech, partial loss of consciousness, confusion of ideas, mental incapacity, giddiness, and vertigo. These conditions are not certainly more easy to accept as the results of a purely functional disturbance of the nervous system than those I have described, with this exception, that certain of the phenomena in my case are permanent. The amblyopia can be satisfactorily explained by the astigmatism, which is mixed, but which can be so far corrected that with prisms and a perforated disc the patient can read  $\frac{3}{8}$ , so that the notion of its being due to any retinal condition may, I think, be dismissed in spite of the dubious nature of some of the notes of the ophthalmoscopic appearances.

It is not so easy to explain the permanent and complete paralysis of the superior rectus or the persistent although very slight degree of ptosis; nor do I feel able to make any suggestions at present which can throw any light upon this singular condition.

## A CONGENITAL ANOMALY OF THE CONJUNCTIVA, HITHERTO UNREPORTED.

By J. F. STREATFEILD, F.R.C.S., &c.

At the Moorfields Eye Hospital, on the 11th of May this year, I saw among others in the crowd of out-patients, a lad who had evidently some conjunctival redness of both eyes, which on examination proved to be nothing but a slight catarrhal ophthalmia. To determine this point, and suspecting it might be a case of granular lids, I looked under the upper lid, and also specially, as usual, to the outer angle of the lower lid on its inner surface. For this purpose I made traction on the skin downwards, and then also somewhat outwards. As I was thus pulling the outer canthus away from the eyeball, and everting the lid, a conjunctival fold came into view, which evidently limited and abbreviated somewhat the normal amount of separation to be effected between the eyelids and the eyeball, the palpebral and ocular conjunctiva, at this part. Then, with another finger, I also lifted the upper lid at the outer angle, and the fold I had observed came very prominently into view. It extended exactly horizontally from just behind and within the outer canthus, to nearly the outer margin of the cornea. It would not allow the lids to be lifted so far as they may be usually away from the eyeball, but the normal movements of the eyes when the lids were *in situ* were not by it interfered with. Being stretched, by lifting the two lids as I have described, the little straight fold was seen to be semi-transparent, and, seeming to consist only of the folded normal conjunctiva, it reminded me of the little vertical fold of mucous membrane under the tongue of infants to which one's attention is so often directed, when, as their mothers and nurses say or suppose, the child is "tongue-tied." In each palpebral aperture this abnormal frænum existed, and was altogether quite symmetrical. There were no other oculo-palpebral prominent folds, nothing like symblepharon in either eye. The patient knew nothing of the anomaly I am describing; he had had nothing the matter with his eyes but the present insignificant conjunctival inflammation. Symblepharon as a congenital affection

has been reported, but the present case cannot possibly, I think, come under this category, because—(1) the conjunctiva was only shortened, or of little extent, directly outwards in either eye, as a little fold forwards and horizontally, instead of a backward and vertical fold. It was not thickened, or otherwise changed in appearance, as are the folds in the reported cases of congenital symblepharon, which seem to have been the result of intra-uterine inflammation, nor did the eyes themselves and the eyelids, excepting as regards these purely conjunctival fræna, show any structural abnormality, any inflammatory results, fetal or otherwise, or any ill-development—if I may assume that these fræna were evidences of ill-development of the conjunctival sacs; because (2) these fræna in my case were only just at the outer angle—i.e., where any symblepharon is not very likely to occur; and also because (3) of the exact symmetry that existed. It was, I think, a partial malformation. I find no notice of any such congenital anomaly in Professor Manz's chapter (vi.) in Graefe and Saemisch's Handbook, or in other books. These fræna may perhaps be explained by a consideration of the development of the eyelids; an upper, lower, and inner lid are formed, of which the latter, although in the human subject it is quite rudimentary, yet it must not now be forgotten, for in the novel and possibly unique case I am recording, the forward folds of conjunctiva were only at the outer canthus and exactly horizontal—that is to say, where without the rudimentary inner third lid, the two greater eyelids come close together into contact, being formed by two, an upper and a lower, infoldings of the integument. If such infoldings above and below, as two pockets, are likely, as I suppose, to leave between the two a tegumentary ridge or outfold, I will venture to guess that I have in the present case found a congenital abnormality not so very rare as hitherto undetected. We constantly open eyelids and look up and down under the two lids, but we do not specially observe if the two lids together are perfectly and normally separable from the eyeball at their junction at the outer angle. Is the common congenital abnormality called epicanthus a (displaced) development of the third eyelid of the lower animals? Is the plica semilunaris in such cases absent? I have not myself observed that it is.

## ON THE VARIETY AND DIFFERENTIAL DIAGNOSIS OF VENEREAL SORES.

By J. CARTER BATTERSBY, M.B., B.Ch. T.C.D.,  
SURGEON, ARMY MEDICAL DEPARTMENT.

As the result of recent research in this country and abroad, and from individual observation, it would appear that two distinct classes of venereal sores exist—namely, first, those that are accompanied with and followed by constitutional symptoms; and, secondly, those that are not. The former have been designated hard or specific, and the latter soft or non-specific. It is, I think, a pity that these terms should have gained such universal acceptance, as they are not only partly erroneous, but liable to lead the inexperienced into much difficulty, and not unfrequently into errors of diagnosis and prognosis. It would be preferable (in the absence of less misleading names) to use the simple and intelligible terms, syphilitic and non-syphilitic, according as the local lesion with its accompanying symptoms presents the characters of a sore from which the constitution will become affected with syphilis or otherwise. As to the duality of the poison, we meet with many eminent surgeons who distinctly affirm that there is but one venereal poison capable of producing venereal sores, and that all such sores are syphilitic. That the constitution does escape contamination in certain cases, is ascribed to the early treatment and administration of mercury, &c.

There was a time when the physician drew no line of demarcation between typhus and typhoid fever, but at the present day there are few who will doubt that the one is as distinct from the other as variola is from varicella. Nor do we now believe that the poison of typhus can produce typhoid, or that of variola varicella. Each is perfectly distinct, has its own period of incubation, its own peculiar symptoms, and individual specific poison. By an analogous mode of reasoning, drawn from the result of practical ob-

<sup>2</sup> Ueber eine Form von Ptosis, Monatsbl. f. Augenheilkunde, 1869, vii.

<sup>3</sup> Ziemssen's Cyclopaedia, vol. xiv. <sup>4</sup> Diseases of the Nervous System.

<sup>5</sup> On Megrim and Sick-headache, 1873.

<sup>6</sup> Arch. Gén. de Méd., June and July, 1878.

servation and inquiry, we are, I think, rationally bound to admit that two distinct classes of venereal sores exist, that each has its own peculiar period of incubation, its own symptoms, and its own specific poison. Is the poison, we may ask, which produces a syphilitic sore and infects the system with syphilis capable of microscopic examination or chemical analysis, and if so, does any perceptible organic difference exist between it and the peculiar specific poison which can only produce a mere local ulcer or ulcers, and which as such are never followed by constitutional symptoms? No solution to the above problem has as yet been satisfactorily determined.

In describing the local lesion or primary syphilitic sore which is always followed by constitutional symptoms, I have usually seen the following three varieties:—

1. *A sore or sores characterised by induration or hardness from the beginning and throughout its entire course.* This first variety may appear as (a) a "cupped-shaped" cartilaginous cavity of variable size, and situated on an indurated base, or (b) it may be seen as a superficial excoriation or elevated elliptical nodule of an ash-grey or livid colour, and generally situated on the corona glandis. Sometimes this first variety appears as (c) an induration beneath the true skin.

2. The second variety (*soft in its early stage, but subsequently becoming indurated*) is seen as a sore or sores which in their early stage simulate the non-syphilitic ulcer or ulcers, but subsequently become indurated and followed by constitutional symptoms. It is exceedingly difficult to diagnose this second variety in its early stage, as I believe it is invariably complicated by the existence of non-syphilitic sores, one or more of which after a variable time may assume the characters of the true syphilitic ulcer or ulcers. The question may arise as to how this peculiar change in the non-syphilitic ulcer takes place, and an explanation be called for. I believe it is due to the existence of a double poison manifesting itself in the one individual, contracted either at the same time (as we know that both classes of venereal sore may exist in the same person) or at different intervals. The period of incubation of non-syphilitic sores being much shorter than that of the syphilitic, they first appear, and whilst being treated the incubative stage of the true syphilitic sore is accomplished, and the lesion becomes manifest. The last case which came under my observation of this second variety of syphilitic sore is worthy of record, as it clearly illustrates the difficulty that attends our early diagnosis.

A corporal in the 4th Dragoon Guards was admitted to hospital under my care suffering from what appeared to be two ordinary non-syphilitic ulcers, situated on the upper surface of the glans immediately in front of the corona. The ulcers were shallow, and had all the characters of the so-called "soft sores." After three weeks from admission to hospital both ulcers became elevated and livid, and presented the appearance of "cupped-shaped" cartilaginous cavities situated on indurated bases; subsequently unmistakable secondary symptoms followed.

3. The third variety of syphilitic sore—namely, *that which is soft from the beginning and throughout its entire course, but followed at a given period by secondary symptoms*—I have usually seen on the external integument situated on the dorsum or side of the penis. When this sore comes under our observation it is generally of two or three days' duration, is circular in form, about the size of a sixpence, edges irregular and sharp, surface presenting a finely granular appearance of a yellow-pink colour, and having a thin ichorous discharge. There is no induration accompanying this sore, either in its early stage or after it has healed, and it is invariably followed by constitutional symptoms. Again, it is our lot to see a sore situated probably on the side of the corona and glans, which rapidly spreads in circumference and depth; the edges seemingly raised, the surface deep and irregular, of a dark or livid colour, and discharging a thin watery fluid. I have been unable to detect any induration about this sore, and have seen it followed by severe secondary symptoms.

Having described and attempted a classification of those ulcers and lesions which I have seen followed by constitutional symptoms, I shall endeavour, under the head of Class II., to point out the non-syphilitic sores which, as such, are never followed by secondary symptoms.

1. *A sore or sores, having a great tendency to multiply, often numbering as many as twenty, and generally situated in the hollow between the glans and the prepuce, on the*

corona glandis, prepuce, frænum, glans, in the meatus, urethra, or on the external skin. These ulcers are first noticed from twenty-four to forty-eight hours after coitus; in some cases, however, they may not appear until the fourth or fifth day. There is generally a good deal of heat and itching about the parts, the ulcers, as a rule, being round or elliptical in shape, and of variable size, very shallow, edges sharp, surface yellowish-pink colour, discharging pus, and surrounded by a narrow red areola. There is no induration from the beginning or throughout the entire course of these ulcers, unless, as sometimes happens, induration occurs as the result of certain local applications.

2. A sloughing sore which may begin as such, or appear so shortly after the ordinary sores are discovered.

3. Gangrenous ulceration or sloughing phagedæna is, fortunately, of rare occurrence; when it does take place the greater portion of the organ may be destroyed. It would appear that an elongated prepuce predisposes to this formidable affection, the upper portion of which first becomes affected. It is, I think, well to give a very guarded prognosis in all cases of sloughing or phagedænic sores. The ordinary non-syphilitic ulcers must not be confounded with herpes or aphthæ of the glands and prepuce, or with what sometimes occurs, a ruptured frænum, the result of mechanical violence. These, as a rule, occur after connexion, have no specific characters, and are unaccompanied by glandular or other complications.

The following table, giving the differential diagnosis between syphilitic and non-syphilitic ulcers, may be useful in helping to form an early and correct opinion of venereal sores.

#### *Syphilitic Ulcers or Lesions.*

1. Incubation ten days to eight weeks.

2. Collateral symptoms: Probable congestion of soft palate and tonsils, slight induration of lymphatic glands in groin, drowsiness, headache, and depression of spirits.

3. Primary lesion or lesions assume some of the varieties described under Class I.

4. Thin ichorous discharge.

5. Generally single.

6. Glands in groin enlarge, but seldom suppurate.

7. Fever present after a short time.

8. Ratio to non-syphilitic ulcers 1:4.

9. Constitutional symptoms invariably follow.

10. Can only have one attack, unless, as in certain rare cases of small-pox, the system, after the lapse of many years, becomes liable to a second seizure.

11. Prognosis unfavourable; must be guarded, and given in accordance with the severity or otherwise of the secondary symptoms.

#### *Non-syphilitic Ulcers.*

1. Incubation twenty-four hours to five days.

2. Collateral symptoms: Probable enlargement and swelling of one lymphatic gland in groin.

3. Ulcer or ulcers assume the characters described under Class II.

4. Discharge always pus.

5. Seldom seen as a single ulcer, and have great tendency to multiply.

6. An isolated gland becomes swollen, and frequently suppurates.

7. Fever absent, unless due to suppuration.

8. Ratio to syphilitic ulcers 4:1.

9. Constitutional symptoms never follow.

10. May suffer repeatedly from such sores.

11. Prognosis (as to the liability of the system becoming affected) always favourable.

AN appeal has been put forth for funds to provide proper medical aid for the sick of Northern India, who, it seems, are deplorably victimised by the ignorant hakims. The services of Dr. Sen, a graduate of the Calcutta University, have been secured by the Cambridge Mission, and to sustain him in the work subscriptions will be received by Mr. Egerton Hubbard, of Cadogan-place, S. W.

A NEW hospital for the isolation and treatment of infectious diseases was opened near Sittingbourne on Tuesday. It has been built at a cost of £5000, and is the first building of the kind erected in Kent, though others are in course of construction, or are contemplated, at Chatham, Maidstone, and Faversham.

## SOME MEDICAL AND SURGICAL USES OF BELLADONNA OR ITS ALKALOID.

By J. H. WHELAN, M.D., M.Ch.

I MAY be excused for making a few remarks on some of the actions of this important medicament without touching on its important effects on the cord, salivary and sweat glands, splanchnics, oculo-motor and sympathetic of the eye, &c. It was called "belladonna" by the Spiniards on account of its being used by the Spanish beauties to dilate their pupils, thus enhancing their personal appearance at the expense of dim vision, fashion ever requiring sacrifices. But while opium may be called the *prima donna* of drugs, belladonna vies with it, and may be called *bella donna* on its own merits with justice. It is well known to physiologists that belladonna and its alkaloid have the power of doing away with the inhibitory action of the vagus on the heart. Physicians and surgeons seem to overlook the fact that syncopic attacks are in the main caused by reflex cardio-inhibition. Every medical man knows that Mr. Schäfer, of University College, has recommended the use of atropine *sub cute* before chloroform inhalation, in order to do away with the effects of the vagus stimulation supposed to be caused by this anæsthetic. Yet how very few use it! I do not know of an Irish hospital wherein the practice has been adopted. We must conclude that the surgeons are sceptical of its good effects. Without going deeply into physiology, let me briefly summarise the evidence of cardio-inhibition, its causes, and the effects of atropine.

1. If we send an interrupted current into the exposed vagus of an animal, after an initial latent period (which is 16 second in the rabbit according to Donders), the heart stops beating and remains in diastole.

2. If we give a dose of atropine before applying the electrodes no such thing takes place.

3. The application of muscarin or pilocarpine seems to produce profound cardiac inhibition, which a small dosage of atropine removes.

4. Nicotine slows the heart considerably, but its effect passes speedily off, the heart assuming its normal rhythm. Stimulation of the vagus has then no effect, but the dosage of muscarine at once produces a standstill. It would seem from this that nicotine paralyses the cardio-inhibitory vagal fibres after an initial stimulation, while atropine, which will remove the effects of the muscarine, has an effect to boot on the heart itself—Bidder's ganglia, or whatever it may be.

5. We may stop the beating of a frog's heart by exposing its mesentery, and slapping it with a scalpel laid on the flat, by crushing one of its limbs, or in other ways, all by causing a reflex action.

What do all these, the results of vivisectional experiments, teach us? They teach us what Schäfer told us long ago, that the hypodermic use of atropine before chloroform inhalation may ward off death itself. But I for one do not believe in Schäfer's idea that chloroform stimulates the vagal inhibitory fibres, but incline to the belief that chloroform weakens the heart's action, that it lessens all protoplasmic activity; that when the shock comes in the cutting, &c., of the operation, we have a reflex cardio-inhibition over which the heart is unable to mount in its weakened condition. We need, in truth, have no operation at all, and this is a point to which I would call special attention. In the administration of the drug when the patient is struggling under its influence, an action in the intellectual centres, the supervention of fright, terror, or any strong impulse may cause a like effect, and death. Should the latter supervene we are treated to the oft-told tale of the failure of the heart's action. Evidently these things may occur under all anæsthetics, and are more potent in those that are of a depressing nature *per se*. They are not specific to chloroform. A dose of atropine would in all cases be a useful preventive, and perhaps, if adopted in future, save some of our species temporarily from the jaws of our grim-visaged foe.

Turning for a moment from Surgery to her kindred sister, Medicine, there are many cases in which belladonna or its alkaloid would prove useful. In some extreme cases of hysteria or allied disorders we have patients going from one faint into another, frequent syncopic attacks. In the allied abnormal condition of pregnancy, that called by old authors

hypothæmia, we have the same condition. In both this drug ought to prove extremely useful. In the former we have impulses originating probably in the higher centres, causing frequent inhibitions; in the latter the less noble organ, the uterus, takes the place of the brain. In certain apparently asthenic inflammations, particularly in peritonitis, a very weak pulse is a common thing. One would imagine that this, which is fast, could in no way be connected with the so-called cardio-inhibitory mechanism, but it is just possible that it might. The inhibitory fibres, being acted on slowly and gradually, become in part exhausted, while the "accelerator" nerves might develop into action. Be this as it may, I once saw a very interesting case under Surgeon Hamilton in the Co. Meath Infirmary. A man was brought in suffering from slight localised abdominal tenderness and obstinate constipation. The pain increased and the pulse became extremely weak and fast, while the constipation increased after the trial of numerous expedients. Surgeon Hamilton ordered him a grain of extract of belladonna every hour. By the time he had taken his second dose the pulse had improved wonderfully, and assumed the normal type in all its characters. The patient ultimately got worse and the pain increased, when he was put on full doses of opium. He died and the autopsy revealed a perforating ulcer of the pylorus. It is difficult with our present knowledge to interpret this case aright. By what means did the improvement of the pulse occur? Was it by the removal of the cardio-inhibitory action developed reflectorally from the inflamed peritoneum? Some no doubt would refer the action to an influence by which the arterioles were contracted *à la* Burdon-Sanderson's theory of digitalis. But leaving this rather difficult problem, I think we have in the deadly nightshade a means by which we can prevent persons from fainting, so that it is just probable, in the future of society, when a young lady feels inclined to faint, instead of running for the brandy bottle recourse will be had to an atropine parvule.

By the introduction of the nozzle of the hypodermic syringe the surgeon may remove the effects of the shocks of gigantic wounds of railway accidents, of common wounds on the battlefield, for the primary shock of the latter sweeps away nearly as many men as their secondary consequences. I had once in the days of my studentship to open a small onychial gathering in a girl's finger. She was of an extremely nervous and erotic constitution, but withal strong and well made. About a year or so before she had been an inmate, for over four months, of a public institution—an inveterate case of hysteria. Immediately after the opening of the minute abscess she fainted three times. Some time afterwards I had to remove the stump of a tooth for her; on this occasion she fainted twice. Less than a month afterwards I had to attempt the removal of another. This latter was the most painful and longest ordeal to her, as owing to the friability of the stump it was extremely hard to be got at. I gave her, twenty minutes before using the instrument, twenty-five minims of tincture of belladonna. She did not faint nor manifest any signs of weakness—a result which must, I think, be attributed to the narcotic. If then, as it seems likely, we are in possession of a drug which will prevent cardio-inhibition, cases of "death from shock" ought to fade from the death register of surgical practice. It is perhaps right to state that Kinger and others consider that the paralyzing action of atropine on the vagus is no longer tenable, though their ideas for thinking so do not seem clear.

Belladonna is sometimes serviceable in annoying nocturnal emissions. It will be found very useful indeed if the emissions be accompanied with erections, but perfectly useless if they be not so accompanied. This is in keeping with Nicolski's results, that atropine paralyses the "dilator" fibres of the nervi erigentes, while muscarine produces erection apparently by stimulating the local dilator mechanism, thus resembling what appertains to the heart. When therefore we have a case of excessive nocturnal emissions with erections, minute doses of belladonna and bromide of potassium will speedily effect a cure when exhibited at bedtime.

Dr. Gentilhomme of Reims, I see by the late journals, has employed a pill containing one-hundredth of a grain of sulphate of atropine in a patient suffering from coryza, and very subject to it, with very excellent results. Fifteen minutes after the first administration all sneezing had ceased, the secretion stopped, and respiration became normal. Eventually the attacks diminished, and finally disappeared under its influence. If Gentilhomme's conclusions turn out

correct, there will be a very decided improvement made in the treatment of catarrh. Dr. G. Johnson's treatment by full doses of opium invariably gives rise to unpleasant sequential symptoms, while Jukes Styrap's frequent minute doses with antimony are very depressing, to which I can bear personal testimony.

Loughrea.

### A WAISTCOAT-POCKET AURAL REFLECTOR AND SET OF SPECULA.

By E. CRESSWELL BABER, M.B. LOND.,

SURGEON TO THE BRIGHTON AND SUSSEX THROAT AND EAR DISPENSARY.

IN comparison with some more favourably situated organs, such as the eye and the skin, the ear is placed at a disadvantage, inasmuch as it usually requires for the diagnosis even of its more common diseases the use of certain instruments. It is therefore of importance that these instruments should be made as simple and portable as possible. A great step in advance in this direction was undoubtedly made when von Tröltsch introduced into general use the aural speculum and concave reflector, by means of which an ear can be inspected either with day light or artificial light. Under my direction Messrs. Millikin and Down of St. Thomas's-street, Borough, have modified these so as to render them still more portable. The reflector (Fig. 1, reduced in size) consists of two circular mirrors, each

FIG. 1.

2½ inch (about 6½ centimetres) in diameter, and firmly jointed together at the edge, so that when folded their reflecting surfaces come into contact. One mirror is made of glass and is concave, having a focal length of 5½ inches; the other is nickel-plated and plane. Both have a central circular aperture. With the concave mirror the ear may be examined either with ordinary daylight or with artificial light, whilst with the plane mirror sunlight may be reflected into the ear. The focal length of the concave mirror is purposely made rather long in order that it may also serve for an examination of the nasal cavities from the front, and for throwing light into the fauces in inspecting that region. With this reflector and a bent hairpin to draw out the ala of the nose a very fair inspection of the nasal cavities can be made. The nest of specula (Fig. 2, natural size) con-

FIG. 2.

sists of three, made of silver, fitting accurately one into the other. They are shorter than those in common use (measuring 3 centimetres—1½ in.—in length), and are made as light as possible. The smaller ends of the specula measure respectively about 6 by 7, 5 by 6, and 4 by 5 millimetres in diameter. The largest speculum, measuring at its broad end 17 by 18 millimetres in diameter, is fitted with a cap, which is preferably jointed on to the flatter side of the speculum, and not to the end of the oval, as shown in the figure. The shortness of the specula does not interfere, I have found, in any way with their practical utility,

although, of course, they afford less leverage for moving them in the ear than the ordinary specula. With these two small instruments in his pocket, the practitioner can, at a moment's notice, inspect an auditory canal and gain important information as to the state of a patient's ear. Others, no doubt, like myself, have frequently been requested to look at So-and-so's ear, as he or she was suffering from earache or deafness. Instead of deferring one's examination to a future period, with these instruments at hand the auditory canal can be immediately examined, and the case prescribed for on rational principles. If, for instance, the meatus be occluded with cerumen, instillations of a solution of bicarbonate of soda can be ordered, which will facilitate its removal with the syringe at the next visit; if the meatus be filled with pus, directions can be given to syringe the ear with warm water; if the meatus be clear, and the membrane shows signs of acute inflammation, or of inflammation in the drum cavity, the immediate application of a leech in front of the tragus will probably be of great benefit, and any other instruments likely to be required, such as the Politzer bag or paracentesis needle, can be brought at a subsequent visit. Without multiplying instances, it is self-evident that, especially in acute cases, such as are met with in general practice, the earlier a case is examined the more successful and satisfactory the treatment is likely to be.

### AN EVACUATOR FOR THE BLADDER.

By JOHN H. MORGAN, F.R.C.S. ENG.,

CHARGING-CROSS HOSPITAL.

IN a lecture published in the number of THE LANCET for January 7th, 1882, Sir Henry Thompson describes an aspirator which had been made according to his own design, and another modification of the same principles carried out by Messrs. Weiss and Sons, and he lays down some points as essential in the construction of an efficient instrument. The first of these principles is that "it should be light and small, so as to be easily grasped and governed by one hand"; the second requires that there should be a tap at the top for the exit of air and the introduction of water. To fulfil these conditions is not an easy matter, since any apparatus of india-rubber which is to support above a heavy tap and be attached below to a cylindrical glass receiver in which fragments are caught, and to which a catheter is attached, must be of such density and size as to be with difficulty grasped, much less compressed by a single hand, at all events many times in succession. In other words, if the continuity of the bulb is broken at two points, its resiliency must be supplied by greater thickness. This objection is practically found in the case of both these instruments. At the late meeting of the Medical Congress in London, Professor Bigelow explained that "the new and essential part of the evacuating apparatus is the large catheter, whether straight or curved," and went on to describe the various apparatus which he has contrived to extract fragments from the bladder, and at the same time to prevent the possibility of their return. These instruments were figured and described in the Transactions, but that Professor Bigelow is hardly yet satisfied is shown by the fact that at a recent meeting of the New York Academy of Medicine he exhibited the evacuator which he has "finally settled down upon as being the best," adding that the ball-valve and strainer which formed part of his former instrument were a "little complicated" and "apt to clog."

Adhering to the principles laid down by these two eminent lithotritists, I have been at some pains to contrive an apparatus which should at once be effective in action, but of simpler construction than those hitherto invented. The result of my efforts is an instrument which is figured below. It consists of an india-rubber bulb (A) of moderate resiliency, and capable of containing about twelve ounces of water. This is of the shape of an inverted pear, and its narrow portion is fixed to a metal ring, which can be attached to or removed from the central portion of the apparatus by means of a screw. This is only required for convenience of carriage or for the purpose of cleaning the apparatus. In order to allow a better view of the glass-receiver, the bulb is attached at an angle slanting backwards to the rest of the apparatus, which hangs perpendicularly. The central portion is of metal,

and forms one with the bulb above, and is attached by a bayonet-joint to the glass receiver below. In front projects a short tube (D), into which the catheter—the largest of Bigelow's sizes—fits when the instrument is in use, but which can accommodate catheters of a smaller calibre. Running diagonally downwards in the interior of this portion of the apparatus, and fixed above, just at the entrance of the passage of the tube (D), is a perforated metal disc, which is placed in such a position that anything carried through the tube (D) must directly impinge upon it, and be thrown downwards. The glass-receiver (C) is made to fit closely to the central portion, and is shaped like the handle of a pistol, with two objects—partly because by this curve an interruption is made of any current of water carrying with it fragments of detritus, and partly because in the forefront of this transparent bowl the size and quantity of the fragments can be seen and estimated by the operator.

In order to fill the apparatus, the receiver (C) must be detached and filled, and the air driven out of the upper portion under water. The two pieces being filled, must be fixed under water, which can be done in a large basin or bucket, and for security the forefinger should be placed over

the mouth of the tube (D), to prevent the escape of any water, although if the instrument is held by the solid portion and inclined slightly backwards, the pressure of the atmosphere is sufficient for this purpose. The india-rubber bulb must not, of course, be touched until the tube (D) has been adjusted to the catheter. It will then be found that the weight of the upper and lower portions is so evenly balanced (when full) as to make all manipulation easy, and entirely under the control of one hand, so that water can be injected into the bladder and withdrawn as rapidly or slowly as is wished, and the position and direction of the catheter altered.

In using this, and all other instruments for a similar purpose, it is well, after forcing water into the bladder, to pause for a second or two before relaxing the pressure on the bulb. By so doing the fragments which have been set in commotion can settle at the bottom of the bladder, and thus come nearer the eye of the catheter, and are withdrawn by the returning current of water. In this apparatus the fragments striking against the metal disc are at once thrown down into the glass receiver, where they remain undisturbed in any position of the instrument. The apparatus has already been used and approved by several London surgeons.

Chapel-street, Park-lane, W.

## STRANGULATED HERNIA OF FIVE DAYS' DURATION IN A WOMAN AGED EIGHTY-FIVE; OPERATION; RECOVERY.

By C. A. OWENS, M.D. BRUX, L.R.C.S.I.

ON Sept. 23rd, 1879, I was called to see M. S—, an old woman, aged eighty-five, who was suffering from sickness and constipation. I found that these symptoms had been present for 120 hours, and were due to the presence of a right strangulated femoral hernia. There was a tense, hard, painless tumour in the corresponding region; she had the usual anxious expression of countenance; pulse 75; temperature 101°. The vomiting was not stercoraceous. Having tried the taxis carefully, but without success, I applied an ice-bag to the tumour, and tilted up the foot of the bed, which proceeding had enabled me to succeed in reducing a hernia under similar circumstances. Later in the day I again visited the patient, and finding reduction impossible, I administered chloroform to her with the understanding that if taxis then failed I should proceed to operate without further delay. Taxis not succeeding under chloroform, I operated in the usual way, being obliged to open the sac, and relieving the stricture by slightly nicking Gimbernat's ligament. The bowel was congested, but retained its natural lustre, and was returned into the abdominal cavity without any difficulty. The wound was closed by sutures, and dressed with a pad of lint supported by a spica bandage. The patient rallied well after the operation, and I left her comfortable, with instructions to take an opiate to procure sleep.

Sept. 24th: Patient cheerful; had rested well without the opiate, which she declined to take, as well as a stimulant in any shape; no pain; temperature 101.5°; pulse 72.—25th: Patient, though uncomplaining, was not quite so well; her temperature had gone up to 103°; pulse 96, and intermittent; no sickness and no tenderness of abdomen.—26th: Patient better; pulse 96; temperature 102°.—27th: Much better; temperature 100°; pulse 112. Bowels had moved naturally without medicine. The patient continued to improve.

On Oct. 1st I removed the dressing, and found the wound entirely healed; sutures removed. From this date the patient advanced rapidly to perfect recovery without any untoward symptom.

*Remarks.*—This case is worthy of notice on account of the very advanced age of the patient (eighty-five) and the length of time the hernia was strangulated. No credit can be given to opium, as she took none either before or after the operation; nor to stimulants for the same reason, the patient having a decided aversion to their use. She was out in the fields gleaming in three weeks, and is alive and well now at the advanced age of eighty-eight. I was assisted by my partner, Mr. Barton, during the operation.

Long Stratton, Norfolk.

## A Mirror OF

## HOSPITAL PRACTICE, BRITISH AND FOREIGN.

*Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.*—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

## GUYS' HOSPITAL.

EPITHELIOMA OCCURRING IN AN ULCER AND IN AN OLD CICATRIX.

(Under the care of Mr. BRYANT.)

THE two following cases are interesting examples of the occurrence of epithelial cancer in old cicatrices. In the first case the ulcer was of about twenty years' standing, while in the second the epithelioma attacked a cicatrix nearly forty years old. These growths mostly affect ulcers on the lower limbs, but in the second of the subjoined cases the scar was in the axilla. Though the epithelioma usually begins as a

papillary enlargement, it sooner or later involves the adjoining textures, and may finally completely penetrate the bone, as in Case 1.

CASE 1. *Epithelioma in an old Ulcer of the Leg; Amputation at Knee-joint; Abscess in Stump; Necrosis; Relieved.* (From notes by Mr. Kendall.)—John G—, aged sixty-two, a cabman, was admitted on April 20th, 1881, into Job ward. He had had syphilis, but he did not know how many years ago, and had otherwise had good health. In the year 1861 he struck his left leg and an ulcer formed, and about 1877 he struck his right leg. In the year 1878 he was in the Plumstead Infirmary, where his legs were poulticed and lotions were applied, resulting in a perfect cure of the right leg. The ulcer of the left leg healed up to the size of a shilling. Both legs got worse after his discharge from the infirmary. About six months before admission into Guy's a quantity of black blood ran from the ulcer in the left leg. He had been in great pain all along. Dr. O'Connor of Greenwich had cauterised his ulcer and cut it.

On admission there was on the left tibia a large growth occupying the lower half of the bone and measuring about six inches from above downwards, and five inches from side to side, and being about three-quarters of an inch above the surface. The inner three-fourths of the ulcer were occupied by the growth, and the outer one-fourth was comparatively healthy; the patient had also a tense hard translucent swelling of the scrotum. Urine had an acid reaction, with specific gravity 1008, and was free from albumen and sugar.

On April 24th, under an anæsthetic, and after an Esmarch's bandage had been applied, an incision was made about an inch below the tubercle of the tibia round the leg. The skin was dissected back as far as the lower portion of the patella. The leg was flexed and the joint opened by cutting through the ligamentum patellæ. The joint was then cut from behind, while the limb was extended. The crucial ligaments were then divided, and the leg was removed. As there was considerable difficulty in twisting the end of the femoral artery, on account of its giving off a kind of axis, a catgut ligature was used. The other vessels were all twisted. The hooded flaps were brought together by silk sutures. Accurate juxtaposition could not be obtained, and so two "ears" of skin were left at the upper part of the wound. A drainage-tube was introduced, and the wound dressed with terebene and put upon a splint. Temperature after operation 98°. An injection of morphia was given.

The tibia was occupied by an epithelioma. At the upper part the medullary cavity, just above the tumour, was filled with new bone, but above this the medulla was normal, and the margin abrupt. Before making the section the bone was continuous across the growth, but it broke during the sawing with very little force. The surface of the bone near the growth was rough and "carious" from new deposit at the posterior surface. The bone abutting on the growth was also eaten out and rough.

On May 2nd the dressings were removed from the stump. The outer ear of the skin was sloughing. There was an offensive discharge, and the patient complained of tenderness on the outer side of the femur. On the 7th there was some gaping between the flaps. A week later the cartilage at the base of the internal condyle had turned black, and was dying. There was a fissure in the centre of the upper part of the tongue, with hard edges having a greyish appearance. On the 23rd a fluctuating swelling had formed over the lower third of the femur on the outer side. The swelling extended about three-fourths of the way round the femur, which bone was denuded of all tissue, except the periosteum and some granulations. The swelling was opened, and a large quantity of pus came away. The cavity was well washed out with iodine lotion. On the 27th there was still considerable discharge from the abscess. The urine was tested; specific gravity 1024, acid, no albumen or sugar.

On June 6th the femur was found to be necrosed for nearly three-fourths of its length. Eight days later there was still a considerable discharge, and a small abscess near the end of the stump was opened.

On July 25th the wounds were healing but slowly. There was a chocolate-coloured discharge from the stump.

On Sept. 5th six skin grafts were applied to the stump wound. On the 12th two small fragments of necrosed bone were removed from the stump.

On Dec. 2nd the left leg had broken down in two places about the size of half-a-crown. There was one ulcer about the size of half-a-crown on the right leg. On the 5th the

patient went out. The sinuses were unhealed, and the parts of the femur were necrosed and in position.

From April 24th to June 21st the temperature ranged mostly from 98° to 100°; once (June 20th) it rose to 102°8', but fell to normal on the same evening. After June 21st it rarely exceeded the normal, and then only to a slight degree.

CASE 2. *Epithelioma of Axilla arising from Scar; Excision; Acute Mania; Relieved.* (From notes by Mr. Manley.)—Eliza H—, aged forty-seven, was admitted on Oct. 11th, 1881, into Lydia ward. She was married, and had had three children. Thirty-nine years ago she was badly burned over the right breast and shoulder. The cicatrization was almost complete, except at a small surface near the anterior fold of the axilla. This remained about the same size until four years ago, when it began to increase in size and to discharge. Seven months before admission it was about the size of a penny, and had extended so that there was a large ulcer occupying irregularly the interior and exterior folds of the axilla. Its edges were hard, everted, and infiltrated, and slightly covered with thin adhesive pus. The base was hard and irregularly granulated. The axillary glands could not be reached, but there were no enlarged glands in the neck. The nipple was destroyed when she was burned; but she stated that milk had oozed from a small hole whenever she had suckled.

On Oct. 25th, under anæsthetics, the growth was dissected away, commencing in the centre of the axilla and extending round the thoracic portion. In dissecting away in the latter part the breast tissue was cut into, and a quantity of creamy pus exuded. Five or six small vessels were twisted during the operation. The growth was removed whole, the disease not having penetrated beneath the fascia. A few cuts having been made in the edges of the wound with a view to remedying the contractions of the old cicatrix, the wound was dressed with eucalyptus gauze. On the morning of the 31st, though the wound was progressing favourably, the patient became delirious, and morphia injections were given by force; and in the evening the patient tried to hang herself.

On Nov. 24th, the wound gave no trouble; but the patient seemed bent on suicide, and was discharged.

The temperature was for the most part about normal throughout. On the evening of Oct. 29th, it attained its maximum of 100°8' F.

#### QUEEN'S HOSPITAL, BIRMINGHAM.

BURN OF ABDOMEN, SCROTUM, AND PENIS, CAUSING PHIMOSIS; CIRCUMCISION.

(Under the care of Mr. WEST.)

EDWARD L—, a stout, single man, aged fifty-three, was admitted, on Jan. 15th, 1882, with deep black eschars over the lower part of the abdomen from the umbilicus downwards, and extending to the scrotum, penis, and both the thighs nearly as low as the knees. While in a state of extreme intoxication on the night of Dec. 30th, 1881, he fell down, and supposes that in his fall a box of fuses which he had in his trousers pocket became ignited and set fire to his clothes. He laid out in a yard all night; and it was only the following morning, on coming to his senses and witnessing the burnt state of his clothes, that he was aware of the serious accident that had befallen him. Carron oil was used to the burns, and gradually the sloughs cleared off; but in the process of cicatrization, phimosis occurred to such an extent that he could scarcely pass his water. To remedy this condition, Mr. West performed partial circumcision after Denmarquay's method on March 3rd. The three silver sutures used to retain the skin and mucous membrane in position were removed on the 10th, and union was perfect by the 14th, a fair amount of preputial covering of the glans being preserved.

The case is of some medico-legal interest, as showing what a grave injury may be inflicted on a man while under the influence of drink without his being aware of it, and of surgical interest, as exhibiting an uncommon cause for the production of phimosis.

SPINAL CARIES; PSOAS ABSCESS; INCISION WITH ANTI-SEPTIC DRESSING AND A SAYRE'S CASE.

(Under the care of Mr. WEST.)

Eileen T—, aged twenty-six, single, servant, a tall well-made, muscular girl, was admitted on December 28th, 1881, under Dr. Sawyer, and transferred to Mr. West's care

on January 7th, 1882. On December 21st, 1881, she started to walk from London to Coventry. On the third day (December 23rd), when about eighty miles from London, she found the road flooded from the recent rains; she went through the water, which was nearly up to her knees; she was in it two or three minutes. When about eighty-six miles from London she found another part of the road in the same condition; this was, as she states, a quarter of a mile long; she says she was in this fifteen minutes. The water was half way up her thighs. She went through both these floods in one day, and her clothes dried on her on both occasions. She complained of the cold from that time and of rheumatic pains in her knees; and on arriving at Coventry, went to bed and remained there till she was brought over to Birmingham. On admission her left thigh was flexed on the abdomen and could not be straightened; she complained of pain in the left lumbar region when pressure or when a hot sponge was applied. A blister was placed over the loins, and iodide of potassium and bicarbonate of potash were given.

January 16th: Extension to limb reaching beyond the knee, with a weight of 21 lb., was applied, and salicylate of soda in ten-grain doses was ordered.

February 15th: The left thigh being much swollen, was punctured by Mr. West and found to contain pus just below Poupert's ligament, to the outside of the vessels.—18th: She was put under chloroform, and the cavity was freely opened below and to the outer side of the anterior superior spine, antiseptic dressing being employed. Over a pint of pus was evacuated.

March 16th: The antiseptic dressing was discontinued. Discharge greatly lessened, and the hardness above Poupert's ligament was much diminished. The circumference of the left thigh was nearly normal.—31st: A Sayre's plaster-of-Paris case was put on, and the patient was allowed to walk about.

On April 28th she left the hospital cured, and without any evidence of angular curvature of the spine.

In this case, cold and exposure had probably set up mischief of an inflammatory kind in the lumbar vertebrae; pus formed and came down the thigh in the sheath of the *pectus* muscle, and was eventually got rid of by free incision. Antiseptic dressing caused this treatment to be carried out without the production of any constitutional excitement, and the immovable plaster-of-Paris jacket enabled the patient to leave her bed and get about in a very short time.

### ST. ALBANS HOSPITAL.

#### SIMPLE DISLOCATION OF THE ASTRAGALUS FORWARDS AND OUTWARDS; REDUCTION.

(Under the care of Mr. RIDGWAY LLOYD.)

On July 27th, 1882, J. S.—, aged forty-three, carpenter, whilst crossing the permanent way of the Midland Railway at St. Albans, slipped upon the metals, twisting his right foot inwards. He was at once removed to the hospital.

On examination it was found that the right foot was considerably inverted, the inner malleolus being so deeply buried in the sole as to be almost indistinguishable, whilst the outer one was exceedingly prominent; neither malleolus, however, was fractured. In front of the outer ankle was a prominence caused by the dislocated astragalus, which was subcutaneous and somewhat movable.

Chloroform having been administered, reduction was readily effected, the bone slipping into its place with an audible snap. The leg was put up on a Neville's splint for a few days, and at the end of nine days from the date of the accident the patient left the hospital, being then able to walk fairly well with the aid of a stick.

Remarks by Mr. LLOYD.—Mr. Bryant, in his "Practice of Surgery," vol. ii., p. 367, remarks that some cases of sub-astragaloid dislocation have been mistaken for dislocation of the astragalus, but the case recorded above certainly belongs, in my opinion, to the latter class, and this view is confirmed by my colleague, Mr. F. R. Webster, who saw the patient with me, and kindly gave me his assistance.

ROYAL COLLEGE OF SURGEONS.—The Library and Museum of this Institution will be closed this day (Friday) for one month; in the case of the latter the time will probably be extended owing to the extensive painting and repairs going on.

## Medical Societies.

### CAMBRIDGE MEDICAL SOCIETY.

At the meeting on August 4th, Professor Humphry, F.R.S., President, in the chair,

Dr. BACON brought forward a case of Hæmorrhage into the Arachnoid Cavity in the person of a woman eighty-seven years of age, and exhibited the specimen. The patient was suffering from senile dementia, but was quiet and apparently in good health. One day she became faint and was helped to a sofa, but had no fall or injury. She became rapidly unconscious, and was at once seen by the medical officer. She never recovered consciousness, had contracted pupils, and died thirty hours afterwards. At the necropsy, the brain weighed from forty-one to forty-two ounces. Over the left hemisphere of the brain, on removing the dura mater, was found a layer of coagulated blood, in a semi-organised condition. There was a similar layer of currant-jelly appearance over the left half of the base of the skull, and extending over the right orbital plate. The cerebrum itself was apparently healthy, and the ventricles contained only a small amount of serum. No ruptured vessel could be discovered, and there was no fracture of the skull or sign of external injury. Dr. Bacon considered that there had been a former hæmorrhage, and that the recent one had proved fatal in accordance with the symptoms related. He mentioned the following cases in connexion with the subject as illustrative:—In Vol. X. of the *Journal of Mental Science* (1865) Dr. J. W. Ogle published two cases of arachnoid cysts occurring in general paralysis, one of which was contributed by him (Dr. Bacon), and remarks on the comparative rarity of such cases. In vol. xi. of the same journal will be found an interesting paper on the same subject by Dr. S. Wilks of Guy's Hospital. Dr. Wilks there approves the theory propounded by Mr. P. Hewett in vol. xxviii. of the *Medico-Chirurgical Transactions*, that these cysts proceed from a "chronic change in a previously effused blood," but in all the cases he gives the symptoms were of some duration.—Dr. PAGET had seen a case of a similar nature in which the symptoms lasted a few days.

Mr. WHERRY related a case of Gall-stones discharged through an Abscess in the Right Groin in a woman under his care. The patient had an obscure swelling in the right inguinal region. An exploratory puncture discovered pus too thick to flow through the cannula, but a free incision let out thick pus and over a hundred gall-stones. The finger passed into the wound in the direction of the gall-bladder. A large drainage-tube was then tied in the opening, through which gall-stones still pass. There was no bile and no faecal odour. The patient had for several years been subject to attacks like ague. A year ago she first noticed in the right side of the abdomen a swelling, which enlarged painlessly until it could not be spanned by her hand. Her bowels were regular, and she had no jaundice. Two months later the swelling appeared, from her description, to burst inside her, and she was immediately seized with violent cramp-like pains in the right lumbar and iliac regions. The swelling diminished, and she had now attacks of vomiting of dark fluid every five minutes for five days, and during this time she ate nothing; but when the vomiting ceased she had a ravenous appetite, and was able to walk about. Altogether she had five similar attacks of vomiting, lasting from three to five days each, followed by several weeks of health. Mr. Wherry mentioned a case of three fistulae from the gall-bladder, which led respectively to the duodenum, colon, and skin. A biliary fistula has been known to communicate through the open urachus with the urinary bladder. Gall-stones are reported to have been found in the right bronchus and in the portal vein. Cases of biliary fistulae opening externally are said by Murchison to occur usually in women, and to be caused by gall-stones, and even when connected with cancer either worms or gall-stones are also found.—In reply to Professor Humphry and Dr. Paget, Mr. WHERRY said that he thought there must have been an abscess near the fundus of the gall-bladder into which the gall-stones were discharged after adhesions in the neighbourhood; that as there was no jaundice and no pain the inflammation was limited to the gall-bladder and cystic duct. No bile came through the external wound, and the patient had a prospect of complete recovery. Columbus

mentions that in the case of St. Ignatius Loyola a gall-stone was found in the portal vein, and an undoubted case has been recorded lately.—Dr. PAGET mentioned the case of a lady he had seen some years ago in a desperate state of illness, when there was great pain and tension of abdomen, and when an incision was made no less than 160 gall-stones escaped, though not all at once. In this case the patient recovered and lived for years. He referred also to another case in which the patient passed a big stone but died from cancer of the liver.

Mr. SHEILD related the case of a lad who had recently been treated in the hospital for Tetanus and recovered as follows:—A healthy country lad, aged seventeen, was admitted on the 30th May. He was suffering from an extensive lacerated contused wound on the flexor aspect of the left forearm, the result of the explosion of a gun. The wound was treated by poultices and carbolic oil, and all went well until June 17th, when symptoms of tetanus set in, with slight stiffness about the muscles of the jaws and of the neck. On June 19th these symptoms had become more pronounced, well-marked trismus was present, with epigastric pains. By June 23rd the disease was fully developed, severe spasms, especially of the muscles of the back, were constantly present, the tongue was foul and the breath offensive, the bowels were constipated, and the pulse quick, while the temperature was high and the urine scanty and high coloured. Excessive sweating was also present, so that an eczematous condition of the cutaneous surface was produced. On July 10th the disease was on the wane. Gradually the spasms grew less severe, the bowels acted naturally, and the appetite improved, while the patient was walking about the ward, with his wound nearly healed, and all tetanic symptoms were gone. The treatment adopted consisted chiefly of generous diet and good nursing. Hypodermic injections of morphia were administered every evening, when the anguish was severe, and caused relief and some snatches of sleep. The bowels were relieved by enemata, and during their peristaltic action the patient seemed to have his sufferings increased, but after the evacuation the pains were alleviated. He smoked tobacco twice, and this gave him some relief from the accumulation of mucus in the fauces.—Professor HUMPHRY had seen a great many cases of tetanus, and had arrived at certain conclusions respecting it. First, that it is a passing malady depending probably, like small-pox, scarlet fever, &c., upon some blood-poisoning, like them being amenable to no known curative treatment, but running a certain course and subsiding, provided it did not kill the patient in its course; that, like them, it is fatal in proportion to the acuteness and severity of its onset. Of the rapidly progressing cases very few survive, whereas in those which come on more tardily, and more particularly in those in which the patient continues to be able to take food, a favourable result may, by good management, not unfrequently be obtained. Secondly, that the disease is attended with much wasting and exhaustion, sometimes with high temperature, and that the most important feature in treatment is to give nourishment, which must generally be in a fluid form, milk, eggs, beef-tea, wine, &c., as much as the patient can take. While food can be swallowed there is hope. It must be urged upon the patient, who is often reluctant to take it, and no other treatment should be allowed to interfere with this. Sedatives, such as morphia hypodermically injected, tobacco, &c., come in as adjuncts more severe cases, but are better abstained from unless the case is severe; and reliance should be placed solely on the feeding, with attention to the bowels, it being generally necessary to give aperients. He had kept patients persistently under the influence of chloroform without any benefit. The maintenance of strength by nourishment, so as to enable the patient to tide over the attack, is the great thing to be aimed at.

Dr. INGLE exhibited a specimen of Cystic Disease of the Chorion. The fœtus in this case was probably eight weeks old, though stated to be five months. There was considerable hæmorrhage between the expulsion of the fœtus and that of the placenta. Dr. Ingle observed that in such cases the diseased state of the chorion may cause the death of the fœtus, though the ovum may be retained for some time longer. The special feature in this case was the abrupt termination of the cord at the amnion, while at another point of this membrane the vessels passed through to the chorion, and this point seemed to be the spot where the placenta originated.

## HEALTH OF THE ARMY.

## No. III.

THE Appendix to the Army Medical Department Reports, containing the professional papers, has just been issued, and is of special interest. The first paper is, as usual, the report on the progress of hygiene during the year 1880, by Professor De Chaumont. On the present occasion this is confined to a notice of the work of Societies, papers, reports, &c., but nothing is said of the legislation on the subject of public health, nor of the special work done at Netley, an omission which is to be regretted. Dr. De Chaumont, in his report, has given a translation of an important paper read before the Medical Society of Munich in April, 1880, by Pettenkofer, "On Cholera and its Relations to the Parasitic Theory," as being "the latest utterances of so distinguished an etiologist, and also because there is much in it that will be both interesting and profitable to medical officers of the public services." He has also brought to notice the facts connected with two outbreaks of typhoid fever—at Pemberton and Orrell in Lancashire, and Ystalyfera in Glamorganshire—with special reference to the question of the influence of the water-supply as the medium of conveyance of the disease. From the surgical division of Netley Hospital we have a list of operations performed during the year, with short abstracts of some of the more important cases, by Surgeon-Major Tobin. We observe with much satisfaction that a valuable paper has been contributed from the medical division by Brigade Surgeon Veale, the Assistant Professor of Medicine, "On Palpitation of the Heart in Soldiers." It would have added to the value of the paper if Dr. Veale had compiled from the records of the hospital a table showing the number of men sent home annually from foreign stations on account of this affection, and the proportion of these discharged as unfit for service. Perhaps he may be able to do so in the next volume, and also to trace whether any change has taken place in the way of increase or decrease contemporaneously with the changes in the organisation of the army. Dr. Veale has examined carefully a hundred patients who had been invalided for palpitation, taken, without special selection, from those who arrived at Netley during the last two years, "noting the antecedents both remote and immediate, the general symptoms, the physical signs, and the probable causes of the disorder, and concluding each examination with such a statement of the actual condition of the heart as a consideration of all the circumstances seemed to warrant." Upon the results of these examinations he has based his paper. We regret to observe that he has not given any of the sphygmographic tracings in these cases, nor do we find any reference to the evidence afforded by them beyond this, that "as a general rule the pulse was weak and of low tension, giving to the sphygmographic tracing a rather high percussion stroke and increased diastolicity." He has tabulated the antecedents of the men as to previous occupation, age, service—at home, within the tropics, and in subtropical climates,—arms of the service, locality where developed, alcoholic drinks, use of tobacco, diseases, and other immediate antecedents, such as marching on active service, overstrain from other causes, and fright. The value, however, of the information, on some of these points at least, is greatly diminished by the absence of any data as to the numbers living among whom the cases were developed. After giving an account of the physical signs, Dr. Veale observes under the head of diagnosis, "The conclusions arrived at with regard to these cases were that there was abnormality at the mitral orifice *without* marked hypertrophy or dilatation, in three instances; that there was abnormality of the mitral orifice, *with* ventricular dilatation, and either with or without compensating hypertrophy in six cases; that there was dilatation without compensating hypertrophy in 48 cases, in two of which there was probably dilatation or aneurism of the arch of the aorta; that there was dilatation with hypertrophy in 19 cases; and that in 24 cases there was no positive evidence from auscultation or percussion *per se* of either dilatation or hypertrophy." He subsequently remarks—"The facts seem rather to indicate that palpitation in soldiers is generally a result and sign of a dilating process which has begun, and is progressing, either subsequently to hypertrophy or independently of and without it, or without a sufficiency of it. Very few, if any, of the cases

answer to the description of the neural form of palpitation, with the exception, perhaps, of those which are induced by excessive smoking. The patients are often not anemic, they eat well, and appear to digest well, yet, on the least exertion, such as running or mounting stairs, the heart beats with extraordinary rapidity." It is this latter circumstance which renders the discharge of the men from the service a matter of imperative necessity. "A few of these patients, after prolonged rest and judicious treatment, may, perhaps, be sent back to the ranks, but they seldom recover thoroughly." Dr. Veale has given a summary of the ascertained or most probable causes of palpitation in the cases he has examined. Of these malarial fever ranks highest, followed by intemperance, heat of climate, marching on active service, exertion generally, excessive smoking, hardships on active service, and several minor causes. He does not consider that the pressure of the valise or of the belts now occupies a prominent place, as it formerly did, although it may still contribute. He speaks very decidedly of the injurious effect of excessive smoking, although he hardly assigns to it as high a place among the causes as we should be inclined to give it, especially when combined with drinking. But it is a cause which it would be extremely difficult to abate, though probably something might be done in the way of issuing less "villanous stuff" to the soldiers than they are in the habit of smoking. "The soldier loves his pipe, and its value as a 'carebreaker' may be, and I daresay is, very great; much caution would therefore be needed in any attempt to curtail this luxury, but in the meantime it would certainly be good economy on the part of Government to insist that such a deleterious substance as the 'twist' or 'stick' tobacco should never be sold in canteens, or issued to the troops on board ship, or in the field." If anyone doubts the injurious influence of this tobacco on the heart's action we recommend him to test it by taking the sphygmograph tracings of even an habitual smoker before and after indulging in a pipe of it. Dr. Veale discusses at some length what he terms "the extraordinary but very general delusion respecting the advantages of flannel underclothing," and he considers the use of it in the tropics to contribute to cardiac disease. We are not disposed to accept his views in opposition to those of almost every medical officer of experience in the Service, and we fail to find in his remarks anything which would lead us to change our opinion on this subject. With the exception of this "delusion," the paper is one which, though on some points defective, is well deserving of study. We trust that Dr. Veale will continue his observations on the subject, and that on a future occasion he may be able to supply the information now wanting.

Dr. Aitken has furnished some brief observations on a case of fractured femur and embolus, which we hope are but the commencement of a series of papers turning to account the great opportunities offered by Netley for pathological investigation.

We have been much disappointed to find that the promised general medical history of the two Afghan campaigns of 1878-79-80 has not been included in this volume. Dr. Crawford's special report on the hospital organisation of these wars, which we noticed when it was sent home as an official memorandum from India, is reprinted; but this does not profess to be a history of the medical and surgical occurrences of the campaign. Dr. Marston's valuable remarks on enteric fever in India are also reproduced; but, as we have already fully noticed both of these papers, it appears unnecessary again to comment upon them. (See THE LANCET of Sept. 24th and Dec. 3rd, 1881.)

There is an interesting report of the Medical Transactions for Natal and the Transvaal during the Boer rebellion of 1880-81, by Deputy Surgeon-General Holloway, C.B., covering the period from Dec. 16th, 1880, when the Boers proclaimed the republic, till March 12th, 1881. There are also reports by the medical officers in charge of the various stations where our troops were besieged, and one by Surgeon-Major Babington of the action at Amajuba Hill, where he was senior medical officer. We cannot enter into the details of these various reports, but will merely note one or two points. At Amajuba Hill the force engaged consisted of 25 officers and 403 non-commissioned officers and men. Of these 3 of the former and 83 of the latter were killed, and 10 and 130 respectively were wounded. During the whole of the Boer war 15 officers and 283 men were killed, and 52 officers and 511 men wounded; of the latter, 10 officers and 69 men, including those of the Naval Brigade, died of

their wounds. The details of the strength are not given sufficiently to enable us to state accurately the proportion of the loss in each class. The wounds admitted into the hospital of the Natal Field Force were classified as follows:—Upper extremities, 113; lower, 108; chest, 28; back and spine, 18; abdomen, 13; face, 9; head, 8; neck, 4; direct injury of large arteries, 2; with direct penetration or perforation of large joints, 9. Of the chest-wounds 8 died, and of those of the abdomen 7; 6 primary and 29 secondary amputations were performed, with 8 deaths. A detailed account is given in a tabular form of the capital operations, and the nature of the injury for which each was performed. Mr. Holloway speaks in the highest terms of the manner in which the medical officers discharged their duties. It is satisfactory to know also that "at no time was there a want of any medical or surgical appliance experienced during the campaign." Dr. Babington has given a report of the circumstances under which the two lamented officers, Surgeon-Major Cornish and Surgeon Landon, were mortally wounded when fearlessly doing their duty.

We have hitherto confined our notice of the volume to the portion relating to the sickness and mortality, but there are other points of importance treated in it. The returns of vaccination among the recruits inspected by military medical officers show that 924 per 1000 bore marks of vaccination, 28 marks of small-pox, and 48 no satisfactory mark of either. In 558 primary vaccinations the proportion furnishing a perfect vesicle was 50 per cent., a modified pustule 27 per cent., and a failure 23 per cent. In 22,721 cases of revaccination the results per 1000 were 417 perfect, 338 modified, and 245 failures. The proportion of failures on revaccination by means of preserved lymph was double that done from arm to arm. Throughout the army at home and abroad there were only 20 cases of small-pox and three deaths in the year.

There were 46,108 recruits inspected for the army in 1880, and the proportion of these rejected as unfit for service was 374 per 1000 on primary and 34 on secondary inspection, making a total of 408. This is considerably above the average, but has probably been the result of an abundant supply of candidates, which has enabled the medical officers to carry out the regulations more strictly. As in former years, the ratio of rejections by army medical officers has been much higher than that by civil practitioners. Upwards of one fourth of the rejections was on account of the recruits being "under chest measurement," amounting to 111 per 1000 examined; the causes next in frequency were defective vision, which gave rise to 48, and "under weight, muscular tenuity and debility" to 30 rejections per 1000. There is one unsatisfactory point in the recruiting returns of the year as compared with those of 1879—an increase in the proportion of recruits under nineteen years of age, in those under 5 ft. 4 in., and in those under 120 lb. in weight, but these are still considerably below the average of the five years 1860-64 (*cite* THE LANCET, Oct. 15th, 1881). The state of education among the recruits examined by military medical officers was: Unable to read, 139 per 1000; able to read but not write, 94; able to read and write, 767. There is no information available respecting those inspected by civil practitioners. There is, fortunately, now in the army an effective staff of regimental schoolmasters to make good the deficiencies in the education of the young soldier.

We cannot close this notice of the departmental volume without expressing our gratification at finding a deficiency to which we alluded last year remedied, and that all the branches of the Netley school are represented this year by papers from either the professors or assistant professors. It would indeed be far from creditable if the great opportunities of acquiring and disseminating special knowledge were not turned to account by men of the high standing and acknowledged reputation of those who constitute the staff of that valuable national institution.

THE sum of £150 is offered to the Rational Dress Society, to defray the expenses of an Exhibition of Rational Dress to be held in London during the coming winter. A Prize of £30 will be given for the dress which best accords with the following requirements:—1. Freedom of movement. 2. Absence of pressure over any part of the body. 3. No more weight than is necessary for warmth, and both weight and warmth evenly distributed. 4. Beauty and grace, combined with comfort and convenience. 5. Not departing too conspicuously from women's ordinary dress.

# THE LANCET.

LONDON: SATURDAY, SEPTEMBER 2, 1882.

LAST week we published the medical report on the health of the crew engaged in the late Arctic Expedition of Mr. LEIGH-SMITH, for which we were indebted to the courtesy of Mr. W. H. NEALE, M.B., M.S., medical officer of the *Eira*. We were, however, prevented at the time from giving the interesting details the full consideration that they deserve; the most remarkable feature being the singular absence of disease amongst a crew of twenty-five men during a sojourn of fifteen months in arctic regions, exposed to great hardships and anxiety. This circumstance reflects the highest credit on the medical officer of the expedition, for it is undoubtedly to his attention to the hygienic and sanitary arrangements during the period the crew were cast on Franz Joseph Land that this satisfactory result must be attributed. It is another instance proving the truth of the observation made as long ago as the time of Captain COOK, that only by an unremitting attention to food, cleanliness, and ventilation, and an early administration of antiscorbutic provisions and of medicines, together with attention to the personal habits of the crew, is it possible to preserve the health and lives of seafaring people on long voyages. It is, as VANCOUVER well remarked, to the attention paid to these principles that Great Britain is in great measure indebted for her present exalted position amongst the nations, and the extension of her commerce through every sea. Unfortunately, however, from time to time expeditions, military as well as naval, have been undertaken without a due regard to the principles enunciated by the great circumnavigator, and these have always ended in failure, more or less disastrous.

Mr. NEALE notices the interesting fact that when the men first began to eat the walrus and bear flesh nearly everyone suffered from diarrhoea, and some of them became very weak. FRANKLIN, in his "Narrative of a Journey to the Polar Shores in 1821-22," frequently records the fact that after obtaining supplies of fresh meat the crew were inconvenienced by bowel attacks, the first alvine discharges being accompanied with excessive pain. On one occasion the men were much more languid and disinclined for exertion than they had been on their previous short commons. FRANKLIN attributes these attacks to the men eating too heartily after having been on a very restricted diet for a long period. This, however, was not the case with the crew of the *Eira*, as they never seem to have suffered actual deprivation. It is therefore a question of interest to determine whether this diarrhoea was the result of passing from salt and tinned provisions to an abundant supply of fresh and recently killed food; or whether walrus and bear flesh, like pork, has a tendency to produce diarrhoea when too freely ingested.

The most interesting of Mr. NEALE's observations, however, is that which relates to the absence of any symptoms of scurvy among the men—a fact which has led him to express the opinion that if men live on the flesh of animals in-

digenous to the country, even without vegetables, they will run very little risk of scurvy, so that under such circumstances lime-juice is not of much use. Curiously enough, while Mr. NEALE is detailing his experience with regard to the prophylactic value of fresh meat against scurvy in the arctic region, Dr. LUCAS writes to us from India, stating that the meat-eating tribes of the north-west provinces are comparatively free from scurvy, whilst the vegetable-feeding tribes are not unfrequently attacked with the disease. This experience of both arctic and tropical observers, which does not stand alone, is so entirely distinct from European experience that some solution of the apparent paradox is required. In a letter which we publish in another column, a correspondent points out that the statements of Mr. NEALE and Dr. LUCAS need not be considered as in any way upsetting our established views with regard to the disease, since, as he urges, meat is probably a scorbutic and an antiscorbutic article of diet according to the period of time that elapses from the time of slaughter to the period of cooking. Fresh muscle, as is well known, has an alkaline reaction, due to the presence of the neutral sodium phosphate; after rigor mortis has passed off the reaction becomes acid, due to the development of lactic acid,—the neutral phosphate is thus converted into acid sodium phosphate. In hot countries the meat is eaten so freshly killed that lactic acid is not developed; in arctic regions the cold stops its formation; in European countries, where meat is usually hung, there is ample time for its generation. Thus in tropical and arctic regions the muscle plasma is alkaline when cooked, in European countries acid. If therefore it be true that scurvy is produced by a diminution of the alkalinity of the blood—a view originally put forward by GARROD and subsequently confirmed and extended by Dr. RALFE,—then we can conceive how fresh meat may be antiscorbutic, whilst hung meat will have an opposite quality. Lastly, Mr. NEALE is to be thanked for his suggestion of the use of blood as an antiscorbutic. If its employment on future occasions should further prove its prophylactic value with regard to scurvy, we shall expect to see it extensively used by our mercantile marine, whilst under any circumstances it introduces to the notice of travellers and voyagers a food at once portable, nutritious, and wholesome.

THE events now occurring in Egypt make any facts bearing upon the health of troops in that country interesting, and a notice of some of the special features of the climate and its influence upon military surgery made by so acute an observer as Baron LARREY may be considered timely. His *Mémoire* refers to NAPOLEON'S campaigns in the years 1798 to 1801, and is full of interesting facts and observations. He had at first to meet with difficulties with which our own military surgeons are not unfamiliar, for when he arrived in Alexandria in 1798 he was unprovided with all necessary stores, the ship in which all that he had carefully collected was contained having been seized by the English in its passage. While waiting at Alexandria the French soldiers suffered greatly from the stings of scorpions, which LARREY speaks of as more alarming than really dangerous; he easily cured them by bathing the part with sea-water or with acid or alkaline lotions.

During a five days' march across the desert to Damanhour, without provisions and without water, the army suffered

terribly, and many died. LARREY specially comments on the absence of all pain in the fatal cases, and the calm that came over them before death; stimulants appeared to be of great benefit to those suffering from extreme exhaustion. Egyptian ophthalmia seems to have been the first affection to arrest LARREY'S special notice. He describes the course and symptoms of the malady fully and carefully. He attributes the disease to the combined effects of bright sunlight, dust in the air, sudden changes in temperature, especially cold damp nights succeeding to hot dry days, the suppression of sweating, alcoholic and sexual excesses, and the sudden suppression of diarrhoea or gonorrhoea. Fair men were found to be more subject to it than were the dark. The treatment he adopted was to commence with bleeding and leeching, and anodyne fomentations, followed by astringent lotions, such as solutions of sulphate of copper, bichloride of mercury, and acetate of lead. The prophylactic measures he recommends are: the avoidance of direct sunlight on the eyes, which should also be protected from dust; to keep the whole body covered at night, with a bandage over the eyes; to avoid damp and marshy places; and to keep up the cutaneous transpiration by baths and exercise. He further recommends taking coffee, the avoidance of spirituous liquors and indigestible food, and states that the eyes and head should be frequently bathed with warm water and vinegar.

After the battle of Sedment LARREY had many cases of tetanus, some of which he quotes. He observed that it most often occurred under sudden and extreme changes of temperature, and in damp situations near the Nile or the sea. Men of a nervous irritable temperament were especially subject to it. The treatment he found most useful consisted in the internal administration of opium, camphor, and nitre, in almond emulsion; externally, the application of blisters to the wound to excite free suppuration; the division, above the wound, of the trunks of all the nerves implicated in the injury or operation; and especially amputation, when the wound was situated on a limb. He asserts that emulsions are swallowed more easily than anything else by patients suffering from tetanus.

In 1799 the plague broke out and made great ravages amongst the troops. LARREY resorted to prompt measures for isolation and disinfection, and obtained satisfactory results. He issued a circular to the army surgeons in which he recommends the treatment he had found most successful—viz., to apply wet cups to the back of the neck and follow them by an emetic, to open and keep open the bowels, and to give bitter infusions and decoctions. Locally, for abscesses he advised poultices, rubefacients, and caustics, and free incisions when pus had formed. When carbuncles formed it was necessary to make deep incisions and remove the sloughs as completely as possible. The great safeguards against the disease he stated to be cleanliness, frequent cold ablutions, and washing of the clothes. He especially condemned as very dangerous the practice of sleeping in pits dug in the earth. The disease prevailed only when the wind blew from the south.

On the return of the army to Egypt after the campaign in Syria a new enemy was met with in the form of a variety of leech that abounded in pools of fresh potable water. These leeches, a few millimetres long, the size of horsehair and

black in colour, by attaching themselves to the pharynx caused great annoyance; when fully distended with blood they attained the size of a common leech. The symptoms produced by these parasites were pricking pain, cough, bloody expectoration, dysphagia, and dyspnoea. At times they were seen attached to the pillars of the fauces, or even lower down the pharynx, but a rather favourite site appears to have been the top of the pharynx behind the soft palate. They were detached by gargles or injections of salt or acid water, or by forceps.

After the battle of Heliopolis and the siege of Cairo in 1800 there was an outbreak of yellow fever among the wounded soldiers, which proved very fatal. It occurred during the prevalence of the hot south wind in the day followed by damp cold nights, and seized mainly upon the less robust of the troops. The wounds of these patients so often and so early became gangrenous that LARREY for a time suspected that the Turks were using poisoned bullets. The prevalence of hepatitis and abscess in the liver likewise arrested LARREY'S attention, and in his article on this subject he especially insists on the great value of free incision into the abscesses when well declared, and he gives some cases showing the excellent results of this practice. Another interesting observation of LARREY'S is the occurrence of atrophy of the testicles in many of the soldiers of the army of Egypt in the year 1799, who noticed after their return to France a gradual painless wasting of these glands, accompanied when both glands were involved by the loss of all sexual desire and power. This occurred quite apart from any previous venereal disease. In most cases only one testicle was affected. This atrophy was accompanied by other signs of disease—wasting and debility of the lower limbs, failure of digestive power, discolouration of the face, thinning of the beard, and intellectual derangement. LARREY attributes the atrophy to the effects of great heat combined with fatigue and privations, and especially to the use of eau de vie prepared from dates, to which the fruits of Solanaceae were added. When the atrophy was only commencing it might be prevented by vapour baths, dry frictions, stomachics, and good food. Leprosy and elephantiasis are well described, and the differences between the two are clearly pointed out. LARREY was greatly interested in elephantiasis scroti, and demonstrated the fact that amputation was the sole surgical resource. He calls the affection sarcocoele, and gives as its causes sitting occupations, the wearing of loose Egyptian trousers, and "degenerated" syphilis. In regard to syphilis, he states that he found the disease to be mild and very easily cured in Egypt, but all forms of inunction were harmful; and if patients returned to France with the disease still uncured it became very intractable. It is interesting to note that while at Cairo, being greatly impressed with the ravages of the disease, he appealed to the Commander-in-Chief to establish a civil hospital in which all prostitutes found to be infected were detained till cured, and all discovered to be pregnant were also detained to prevent their procuring abortion. A strict inspection of the men was also made, and all affected with venereal diseases were kept in hospital. These measures were crowned with complete success.

Wounds were found to heal with great rapidity, and many cases of very severe injury in which recovery ensued testify

to the general salubrity of the climate. This was especially the case during the prevalence of the north winds, and was so marked that LARREY frequently mentions the fact. It was observed that gunshot wounds of the arm, causing fracture of the humerus, were nearly all followed by false joint. In cases of penetrating wounds of the lung he departed from the practice usual at that time, and closed the external wound, laid the patient on the injured side, and enjoined strict rest, and his results were very good.

LARREY observed with interest that although dogs abounded in the Egyptian cities, there was no hydrophobia among them. Camels, however, suffered from a form of madness during the time of rut, and bites from them in this state were dangerous, but the disease was not contagious. The symptoms were the escape of an abundant thick saliva, constant bellowing, horror of water, wasting, fever, falling off of the hair, and bad temper, which showed itself by their pursuing men and other animals. If excited, the symptoms increased, and often ended fatally. Horses were subject to ophthalmia like the men, but this could be prevented by shutting up the stables during the cold damp nights.

The last scourge of the troops was scurvy, which broke out in 1801, and, owing to its being thought to be contagious, produced great alarm. This mistake LARREY quickly corrected in a circular, addressed to the military surgeons, in which he points out that the disease was caused by the want of fresh meat and vegetables, the predisposing cause being a nearly constant humidity of the air after the overflow of Lake Madjeh. Over 3500 cases of scurvy were received into the hospitals at Alexandria, of whom 272 died, exclusive of six or seven who lost their lives while returning to France. During the prevalence of scurvy there was hardly any plague, and the Egyptians had observed that when small-pox was epidemic there were very few cases of plague.

IN a recent article in the *Globe* it is stated that "the Army Medical Department can hardly be in a satisfactory condition, as far as numbers are concerned, when a little war like the present drives the authorities into employing civil practitioners at the cost of 17s. a day. And yet this is the present condition of affairs at most of our military centres. What would be the state of things, we wonder, if a second corps d'armée had suddenly to take the field?"

It can hardly be supposed that a department like the Army Medical Service ought in time of peace to be kept up to a war establishment. The country would not care to incur the very heavy expense involved in such a proceeding unless upon the plea of urgent and imperative necessity, and it would certainly be an act of most unnecessary extravagance. One of the objects which the Government had in view in the recent reorganisation of the department was to have a corps of efficient, well educated medical officers employed in taking care of the soldiers in time of peace, under such conditions that they could be mobilised at once if their services were required in the field. And the events connected with the present campaign have most fully justified the steps then taken. On the outbreak of hostilities a sufficient number of medical officers for the force employed was at once available, and there was neither delay nor difficulty in despatching them to the field when their services were

required. As a matter of course, their place at home must be supplied, but this also had been foreseen. It was considered by those most competent to judge that it was of the greatest importance to send well-qualified officers, having practical experience of soldiers, to the front, and to supply their place at home, temporarily at least, by obtaining the services of civilian practitioners. To what extent it has been necessary to do this we are not aware, but if a second corps d'armée were, as our contemporary has suggested, suddenly called to take the field, we have no doubt the Army Medical Department would be able to supply the requisite number of surgeons, and would replace them in charge of the troops at home by the aid of the civil branch of the profession. If this has been done "at the cost of 17s. a day" for each officer removed, we can only say it has been a very satisfactory arrangement for the country. Were a higher rate of remuneration necessary, and at some of the larger stations where there is a considerable body of troops it probably would be required, we still think it would be much more economical than keeping up in times of peace an establishment sufficient to meet the possible demands of war, and more judicious than maintaining permanently a large number of half-employed officers, who would be undergoing a progressive deterioration in their professional knowledge from want of opportunity of keeping it up, and in their moral and social habits as a consequence of their enforced idleness. The arrangements of the medical service have up to this point been very satisfactory, and we have little fear that they will continue to be so, even though it may involve a considerable outlay. If we are to go to war we must be prepared for a liberal expenditure of money, and surely that which is incurred to keep our soldiers efficient in the field, and to afford them prompt and skilled assistance when wounded or struck down by disease, is the least likely to be grudged by the country.

THE sad fatalities which have attended the boating and bathing season this year have attracted attention to the best means of restoring animation to those apparently drowned. Considerable improvement has been made upon the rough-and-ready method in vogue in the Royal Navy at the end of the last century, which consisted in rolling the body to and fro over a cask, tying it by the legs with the head downwards, and the employment of other rough methods with the object of disgorging the water. LIND, who was physician to Haslar Hospital in 1774, endeavoured to introduce a more humane, and certainly a more scientific one, since he directs that air moderately heated should be pumped into the lungs by means of bellows; whilst a "gentle alternate pressure and dilatation of the ribs, with a corresponding alternate compression of the contents of the belly upwards, imitate as nearly as possible the act of respiration in the living body." To MARSHALL HALL, however, belongs the undoubted credit of devising and successfully introducing a method of treatment for restoring the apparently drowned at once practical and scientific. Dr. SILVESTER improved upon this by adopting the plan of alternately raising and depressing the arms, by which a greater amount of air is admitted into the thorax. Lastly, Dr. HOWARD, of New York, has introduced a system which has recently been investigated and reported on by the Royal Medical and

Chirurgical Society on behalf of the Royal Humane Society. Dr. HOWARD'S method, in its essential details, resembles that proposed by LIND, in the alternate compression and dilatation of the ribs, &c. No doubt, in skilful and well-trained hands, Dr. HOWARD'S method proves a most successful agent in the recovery of the apparently drowned, but it requires some skill to direct efficiently and effectually the alternate movements of the chest walls, whilst rough and unskilful operators might cause injury to the abdominal viscera. SILVESTER'S method is free from these objections; it is easily practised, and there is no manipulation of the body. In the experiments of the committee of the Royal Medical and Chirurgical Society it was shown that more air passed through the lungs by simply raising and depressing the arms (SILVESTER'S method) than by the compression of the lower part of the thorax (HOWARD'S method). Nevertheless we think a combination of the two methods would give the best results. HOWARD'S plan of emptying the stomach, and perhaps the lungs, of water is the best yet devised, whilst gentle alternate compression and relaxation of the lower end of the thorax is a valuable supplement to the effect obtained by the alternate elevation and depression of the arms. In no case, however, should that procedure be omitted. One point, however, with regard to the restoration of the apparently drowned should not be forgotten—namely, that the asphyxia will very often recur if the patient after apparent recovery is allowed to get up and walk home too soon after his return to animation. In dealing with the question of the preservation of life from drowning, the old adage, "prevention is better than cure," occurs to us with its usual force. We are unable to quote offhand the statistics which show how many lives would have been spared had the victims of the fatality been able to swim—we believe it has been stated at more than one-half,—whilst a considerable number of those unable to swim would have been able to save themselves had they had appliances within reach. Considerable attention has of late years been paid to the construction of life-saving garments, and these can now be fitted for ladies' jackets, capes, and corsets, for gentlemen's vests, pea-jackets, and oilskins. For ladies in the habit of boating WENTWORTH'S sleeved corset might be recommended not only as a useful article for the purpose for which it is designed, but also as "æsthetic" in appearance. The use of a preserving article of dress may turn the scale in favour of life in many a shipwreck or collision; since it often happens that if persons can keep afloat only a few minutes they will be rescued, whilst those who may be cast on shore after shipwreck will certainly be less likely to receive injury from the violence of the waves if the abdominal and thoracic cavities are encased in the elastic armour these belts afford.

To take a tracing from the radial artery with the sphygmograph is not always a very simple matter, but its difficulties are far slighter than are those which present themselves when the tracing is to be interpreted. Up to a certain point the task is easy and the conclusions open to little doubt; beyond this, however, there is much uncertainty regarding the precise significance of the lines and curves which constitute the self-written record of the labouring heart. Even some of the fundamental principles are still undecided, and

the positive assertions of one authority are met by the contradictions, equally positive, of another. Under these circumstances, it is worth while to direct attention to an original study of sphygmographic principles which has been made by a German physician, Dr. GRASHEY, and described by him in a volume published at Leipzig. His conclusions are not in the main new, but they corroborate and extend previous results, and have in some instances been reached by methods more exact than those employed by some of his predecessors in the same work.

Commencing his investigation with an inquiry into the accuracy of MAREY'S sphygmograph and its modifications, which still, in spite of the energy of inventors, constitute our most trustworthy instruments, he soon arrived at the conclusion that, while slow movements are recorded with accuracy, quick movements are registered in exaggerated extent. He has determined at what point the inaccuracy commences. As long as the maximum rapidity of movement of the writing lever is under 90 millimetres per second the register is accurate; but when the rapidity exceeds 120 millimetres per second the record shows a movement too extensive: the writing lever rises from the fulcrum, which it should follow accurately, and then falls again, so that we have a rise and fall, instead of a slighter rise followed by a horizontal line, the fall and the corresponding part of the rise being purely artificial. Artificial oscillations may thus have their origin in the instrument; but they may also be produced by an elastic tube if this is used to convey the impulse from the source to the register, and GRASHEY has determined the point at which the recoil of the tube introduces an artificial element in the resulting tracing. It is met with when the movement of the wall of the tube has a rapidity of seventy-three millimetres per second. These artificial oscillations modify the tracing at the upper end of the up-stroke of the lever, and not in the course of the up-stroke; and, similarly, other oscillations of like origin occur at the end of the down-stroke, but not in its course.

These facts having been ascertained, GRASHEY next investigated the simple wave-movements of elastic tubes. The method adopted by LANDOIS for the production of these movements consisted in the sudden constriction of the vessel at one spot, but this involves a source of error, since the wave thus produced, positive or negative, is preceded by a slighter wave of the opposite character. GRASHEY, to obviate these, produced a positive wave by opening a stopcock, and a negative one by suddenly allowing water to escape from the open mouth of a tube in connexion with that to which the sphygmograph was applied, or by the sudden interruption of a current flowing continuously through the tube. Care has to be taken to avoid the complicating effect of reflected waves, which, if the tube be short, may pass through it more than once. From his experiments on this subject he arrived at the following conclusion. In a completely closed tube, a primary wave is transformed into a reflected wave of the same character. In a completely open tube, the reflected wave is of the opposite character to the primary wave. In tubes which are partially open, each primary wave is transformed into two reflected waves of opposite characters. If a second tube is attached to the primary tube, each being filled with water, and a wave is sent from one to the other, a part of the primary wave is reflected from the junction as a wave

of the same character, provided, with equal extensibility, the area of the second tube is smaller than the first, or provided, with equality of area, the extensibility of the second tube is less. If, on the other hand, the second tube is wider, but of the same distensibility as the first, the primary wave passes on, but causes a reflected wave of opposite character from the point of junction, and this wave is so much the larger the more the second tube exceeds the first in area and extensibility. The laws which regulate the movement of waves upon the free surface of water, as regards intersection, intensification, and diminution, obtain equally for waves within a tube. Moreover, a wave set up in a ramifying tube passes into all its divisions.

Applying these considerations to the physiological phenomena of the circulation, GRASHEY points out that each systolic positive wave will be followed by two negative waves. One of these, the "first diastolic depression," is that which occurs at the termination of the flow of blood from the ventricle into the aorta. This really occurs during the systolic interval, since the flow of blood ceases some time before the relaxation of the ventricle. The second diastolic wave coincides with the end of the systole. If, however, as is sometimes the case, the systole is imperfect, and the ventricle is not completely emptied, the cessation of flow occurs at the same time as the end of the systole, and these two negative waves will coincide. The second diastolic depression is, of course, immediately followed by the positive wave, which is produced by the closure of the aortic valves, and to which is usually ascribed the rise which interrupts the down-stroke of the tracing. These four waves pass centrifugally along the vessels, and at each division will give rise to reflected waves, of the same or of opposite character, according to the laws already mentioned. The resulting "interference waves" have, according to GRASHEY, an important influence on the phenomena of dicrotism. Other things being equal, the dicrotic wave will be highest when the ventricular systole is short and imperfect, and the cessation of the flow of blood coincides in time with the cessation of the ventricular pressure, and the wave will be least when the interval between the two events is greatest. Moreover, heterogeneous reflected waves will increase the degree of dicrotism, and homogeneous reflected waves will lessen it. But heterogenous reflected waves tend to occur if the arterial twigs are dilated and extensible, in consequence of the lessened vascular tone, which entails a fall in the blood pressure, as in fever. Hence it is intelligible how a short primary wave, diminished tension, with normal elasticity of the vascular wall, increase the amount of dicrotism.

WITH a view to increased efficiency in the sanitary administration of the Province of Ontario, a Provincial Board of Health has been established. The Act constituting the Board provides that it shall consist of seven members, including the secretary, and in view of the fact that the Board is to take cognisance of the interests of health and life among the people of the province, it is enacted that at least four members of the Board shall be duly registered medical practitioners, and that the secretary shall be the chief health officer of the province. The Board is required to make a full and complete use of the collected records of deaths and of sickness among the people, to make sanitary investiga-

tions into the causes of disease, and the origin and prevention of epidemics, to advise the Government in regard to public health, and as to the best methods of improving health by means of such works as drainage, water-supply, the removal of excreta, heating and ventilation of dwellings, &c. Where necessary the Board is authorised to make special investigations on oath, and it is also required to keep an adequate supply of vaccine matter. Under the same Act municipalities and local boards of health may provide means for the isolation of the infectious sick, and provision is made for the removal of patients to the hospitals so provided. In this respect the Act is in advance of our Public Health Act, for it distinctly enacts that the health authority, or their officers, may isolate any person suffering from a disease dangerous to public health, and this without the qualification which in our own Act has so often proved a source of hindrance—namely, that the patient must be without proper lodging and accommodation. The Ontario Act in this respect recognises the importance of protecting the health of the public, whilst the English Public Health Act, as generally construed, deals rather with the necessities of the patient. The Provincial Government have also settled the question of the compulsory notification of infectious disease in a manner which would certainly not have gained favour in the mother country. Not only is every householder obliged to give notice to the local board of health, or to the health officers of the district, when any member of his family is found to be suffering from a disease dangerous to the public health, but any physician called in to such a case is bound immediately to give a similar notice. Failure to report is punishable by a fine, and no fee for notification is provided for.

The new Provincial Board of Health has already shown itself in earnest. It has issued a series of notices to municipalities and public bodies calling attention to its own and to their powers in health matters. It has circulated amongst school teachers, ministers of religion, and others very valuable advice on the prevention of epidemic disease, and it has asked for information from the various authorities as to the existence within their respective districts of by-laws as to the construction and position of wells, privies, waterclosets, drains, &c., as to scavenging and other matters. So desirous is the Board of acquiring all available information as to disease prevalence, that it has prepared a series of cards on which medical practitioners are asked week by week to fill in the sickness records of their practices together with certain other information. This information, like that relating to infectious disease, will, it is evidently expected, be given without any fee, and we are bound to confess that in this respect the Board is expecting too much of the medical profession. That the information asked for is wanted in the interests of public health we do not for one moment doubt; indeed the lack of proper sickness returns is now universally recognised as a serious want in connexion with sanitary administration. But a public want should be met out of the public funds, and it is clearly unreasonable to ask that members of a busy profession should at the sacrifice of much valuable time, and without any fee or reward, supply a public body with information which will need to be carefully compiled. In England, medical officers holding Poor-law appointments are required, in virtue of their official

position, to supply such information, but it has never been so much as suggested that a similar demand should be made of private practitioners. Indeed we know of no other profession to whom any such request would be made. One other very important initial step has been taken by the Provincial Board. It has deputed Dr. COVERTON to visit this and other European countries with a view of learning the experience of the older established State Boards of Health. Dr. COVERTON has spent some time in this country; he will attend the International Congress of Hygiene at Geneva in his official capacity, and it is evident that he will carry back with him abundant materials for aiding his Board to arrive at decisions with regard to their future course of action. It would be well if our own Central Health Authority were in this respect to follow in the wake of the new Canadian Board. The experience of other countries, and especially that of some of the National Boards of Health of the United States, would, if it were acquired and properly compiled by skilled officers with a view to its being made use of in this country, afford in many respects most valuable aid to efficient sanitary administration.

## Annotations.

"Ne quid nimis."

### HEALTH OF H.R.H. THE DUKE OF ALBANY.

IT is with great regret we hear of the illness of His Royal Highness the Duke of Albany. Prince Leopold is known to suffer from constitutional weakness, with liability to hæmorrhage—hæmatophilia. Of this malady he has recently had an attack. Hæmatophilia ten years ago had no place in the College of Physicians' "Nomenclature of Diseases." The malady is interesting for several features other than the tendency to spontaneous hæmorrhage, or to bleeding from slight traumatic causes; such, for example, as the great proclivity to painful swelling of the joints, dependent or not upon injury, the fact of the morbid condition being in many cases congenital, and its hereditary transmission, to males especially. All these points have been fully dealt with by writers, but it may be useful to say a few words about them again here. The joint affection was well illustrated in a case communicated to the Clinical Society by Sir William Jenner during his presidency. (THE LANCET, November 18th, 1876, vol. ii., p. 716.) Sir William, in the course of his remarks on the case, spoke of the joint affection in hæmatophilia as being of three varieties—viz., a spontaneous swelling, with tenderness and but little effusion; large effusion, with or without hæmorrhage; and serous effusion simply, this last being the rarest. The occurrence of blood in the cavity of the joint does not appear always to be related to traumatism, but the great liability to severe joint affection following slight injuries accords with the similar proneness to cutaneous hæmorrhage. As to the nature of this remarkable condition, everything points to its being dependent on some congenital defect in the vascular system, not necessarily inherited, but at the same time most liable to be transmitted by inheritance when once it appears. Such observations as have been made on the blood do not show much marked alteration in its constitution. Sir Wm. Jenner, speaking on the occasion to which we refer, seems to have thought the blood was slow in coagulating, but this alone cannot explain the liability to hæmorrhage. Another fact, also alluded to by Sir Wm. Jenner, is that the bleedings occur often when the patient is most healthy; and he believed that in these sub-

jects blood is formed rapidly, and there is a tendency to plethora of the smaller vessels. The most important fact of all, however, is that which concerns heredity in this disease. In its proneness to be transmitted by inheritance hæmatophilia occupies a foremost place, and this fact of itself seems to show that its nature is rather a defect or abnormality in development than an actual morbid process.

It may be hoped that the present indisposition of the Duke of Albany is not of serious character, and that His Royal Highness will make a good recovery; but it is abundantly evident that the avoidance of any considerable exertion must be continued for some time to come, and the Duke will need to regard himself as an invalid. Since his marriage His Royal Highness has made a laudable and highly appreciated effort to assume a full share of those toils of State which, in England, have for many years devolved on the younger members of the Royal family. Treading in the footsteps of his illustrious and lamented father, Prince Leopold has striven to fill the place the untimely death of the Prince Consort left vacant in the patronage and encouragement of science, art, and literature; a place and work of light and leading which Prince Albert created for himself, and by which he conferred inestimable benefits on important, perhaps the most important, classes in this country. The Heir Apparent has done much to carry on the truly philanthropic enterprise originated by his Royal father, but, looking to the arduous task which circumstances have combined to thrust on the Prince of Wales, it was impossible that his Royal Highness should make a specialty, such as the late Prince Consort made, of the encouragement of art and letters. The Duke of Albany, whose personal tastes are of a scholastic character, has with marked and admirable energy devoted himself principally to this work. The state of his Royal Highness's health clearly necessitates more than ordinary caution in the expenditure of strength. The care which the Duke of Albany is receiving from those about him is likely to carry him safely through the present trouble, and such self-restraint as he must be enjoined to practise rigorously in the future will, it is hoped, be successful in preserving a life which, like that of every other member of the reigning family, is dear to the heart of a loyal people.

### THE LIFE RISKS OF NON-COMBATANTS.

IF medical officers in the army are "non-combatants," and, therefore, not entitled to the honours of the service, they are evidently exposed to its most deadly risks. During the last engagement in the campaign now in progress, at Kassassin, only one officer was killed, and in this single casualty the medical profession has lost a member. Surgeon-Major Shaw, of the Army Medical Department, is the victim. We have no particulars at the time of writing, but it is manifest that this "non-combatant" was at the front, and in danger. It is a spirit unworthy of the British army and discreditable to gentlemen, that denies the medical officer his due rank, but it is some grim consolation to know that by the appearance of names like the present in the list of killed, the truth must in process of time be made plain to the nation—which, after all, is the true source and fountain of honour, let us disguise the fact as we may. As a matter of experience, the medical officer is, in a double sense, combatant. He fights the worst foe of men in campaigning—disease; and while it may be only occasionally he has to contend with the enemy on the field of battle, he is daily exposed to the same life risks as those who desire to monopolise the credit and privilege of combatant rank; and let us boldly assert that without the excitement of the same of war, which enables these officers to play the part of heroes, the medical officer is their peer in personal courage as he is their equal in the chances of injury and of death.

## THE ILLNESS OF THE PRIMATE.

THE condition of the Archbishop of Canterbury excites grave apprehension on the part of his friends. It appears that his Grace has been failing in health for some months past. He had an attack of bronchitis of a gouty character in the autumn of last year, and, as our readers will remember, he sought rest in the neighbourhood of Bordighera in the spring. He returned after Easter somewhat better for the change, and devoted himself as usual to the duties of his office without thought for his own weakness. The gouty condition, however, developed itself in different parts of the body. Thrombi formed in the veins of the leg, and evidence of valvular insufficiency presented itself. On August 7th he was able to visit Osborn, where the Royal Princes on the following day underwent the ceremony of confirmation at his hands, and on the 9th he returned to Addington Park. He had a slight rigor on the 11th, and when visited by his medical attendant was found to have a rise of temperature, increased frequency of respiration, and a pulse of 96. There was slight pain in the left side with dullness on percussion over a large portion of the base of the left lung, and indistinct bronchial breathing, but without crepitation. On the right side the breath sounds were rougher than natural. The pain in the side ceased the next day. On the 16th there was a repetition of the rigor, followed by pyrexia and the development of minute crepitation on the base of the right lung. On the following day the respiration was 40; temperature 101.5°; pulse 96. The cough was scarcely felt and the slight expectoration of glairy mucus tinged with blood, which began on the 11th, ceased on the 19th, and has not since been at all troublesome. He was visited on the 25th by Sir W. Jenner. During the last few days the breathing has continued to vary between 36 and 40, the pulse between 88 and 108. The temperature, sometimes normal in the morning, has risen every day to 100° or 101°. The Archbishop is drowsy and sleeps much, whilst the mucous membrane of the throat is dry and sore. Food of a light, nutritious, but unstimulating character is eaten regularly and in good quantity. There have been occasional tremors in the arm which was paralysed fourteen years ago, but no cerebral disturbance. The diagnosis is thrombosis in the left lung to a considerable extent, with slight pneumonia on the right side, congestion of kidney of a gouty character, with increase in the hypertrophy of the heart, following an attack of pericarditis many years ago, when he was headmaster of Rugby School. The energy which his Grace has evinced during the time he has been Primate, notwithstanding his bodily ailments, cannot but be regarded as remarkable.

## MURDER BY POISONING.

ATTENTION is directed to a little village in Hungary, where, until recently, as alleged, a gipsy woman, now seventy years of age, has for a long time carried on a prosperous trade as poisoner. Upwards of a hundred husbands or lovers are said to have been "done to death" under the directions and with the aid of this malevolent hag. By the treachery of her daughter the culprit has at length been brought to justice. The medical aspect of this case has not yet assumed a form which would justify us in making it the subject of professional remark. The most we know of the affair, and that solely from common report, is that the poison employed has, thus far at least, eluded the measures taken for its discovery. "Even now that the bodies of some of her victims have been exhumed, they show no signs of poisoning, though the stomachs are eaten away." It is stated that the destroyer of life "excited no suspicion because the drugs she administered acted slowly, though surely, and in their effects simulated the symptoms of disease." This is the hideous and

significant feature of the case, giving ground for more than common dread lest the black art of the Eastern poisoner should find its way into Western Europe. It is an unexplained but most happy circumstance that, although European communities are every now and again demoralised by the revelation of some atrocious case of poisoning, that mode of murder has not, and let us hope never will, become naturalised amongst us. The hideous and manifold possibilities of death being brought about by means which cannot be detected by the victim or those around him are enough to scare any community. It is well that we in England have no ground for serious alarm in regard to this crime of secret poisoning. At the same time, it is wise to be ever on the alert. It may be doubted whether, with all the perfection of our vaunted system of Registration, we are as secure as we might be if only more attention were bestowed on *all* cases of chronic or slow disease of anomalous character. It is in connexion with maladies of this nature danger lurks. It cannot be disguised that there are deadly substances capable of inducing changes of tissue that must end in the death of the organism into which they are introduced. Against the administration of these "poisons" there is practically no safeguard. The scrutiny to which mysterious maladies are subjected cannot be too close, and it would tend to the triumph of justice over skilled crime, if attention were less exclusively directed to the recognition of those known mineral and vegetable drugs which are classed as poisons. It is not desirable to say more than this; but so much may and ought to be said in the interests of public prudence and the security of human life.

## THE ANTIQUITY OF MAN.

THE present condition of our knowledge in regard to the antiquity of the human race was interestingly summarised by Professor Boyd Dawkins in his address to the Anthropological Section of the British Association. He referred to the rudely chipped flints left by the early hunters in the gravel beds of Hampshire and Wiltshire, when Southampton Water had not yet come into existence, and its site was traversed by the elephant and the reindeer; when the Isle of Wight was still a part of the mainland, and the river-drift hunter could walk across from Portsmouth to Cowes with no obstacles beyond those offered by rivers and morasses. He pointed out that the most striking feature of the Tertiary period is the gradual and orderly succession of higher types of the mammalia, which, indeed, is so well defined that he has used it as a basis for the classification of this period. Professor Dawkins' own observations, combined with those of Prestwich and others, show clearly that the placental mammals become more and more specialised as we approach the frontier of history. The living Orders appear in the Eocene, the living genera in the Miocene, a few living species in the Pliocene, and the remainder in the Pleistocene. He traced the evolution of living forms in the ascending order in point of time, commencing with the historic period, our knowledge of which was based on documents, refuse heaps, and tombs. This period was preceded by the prehistoric, in which domestic animals and cultivated fruits appear. Man was then numerous; he could spin, weave, make pottery, and mine. He could obtain iron and make bronze; and left as traces of his existence camps, habitations, tombs, and refuse heaps. Before this, in the Pleistocene period, man appeared as the palæolithic hunter, and some knowledge of him could be gained from refuse heaps and contents of caves. In the age immediately preceding the Pliocene, the living species of placental mammals appeared; there were apes and simiads in Southern Europe. In the Miocene apes and simiads existed in Europe and North America. In the Eocene the placental mammals now on earth were represented by allied forms belonging to existing orders and families. Thus it appears that the orders,

families, genera, and species of mammals, when traced forward in time, fall into the shape of a genealogical tree with its trunk hidden in the secondary period, and its branches represented by the living species passing upwards from the Pliocene, a tree of life with living mammalia for its fruit and foliage. The hiatuses or intervals might be filled up with extinct species. The marsupials began their specialisation in the secondary period, and already in the Eocene period had arrived at the stage which is represented by a living genus, the *Didelphys* or opossum. It will be seen that Prof. Dawkins does not claim for man a higher antiquity than the Pleistocene period, which is equivalent to the Quaternary of the French and the Post-pliocene of the early works of Lyell, and he considers that the views of Capellini and Whitney, referring man to the Pliocene period, rest on unsatisfactory evidence. He enumerates the animals that made their appearance with man, such as the mole and shrew amongst Insectivora; the mouse, beaver, hare, and marmot amongst Rodentia; the cat, wolf, and fox amongst Carnivora, with many other animals of active habits; animals inhabiting the cold climate of mountains, and certain animals like the porcupine, hyena, lion, and panther, now only found in warm climates; and, lastly, certain extinct animals like the mammoth, woolly rhinoceros, and cave bear. He described the buried forest of Cromer and the adjoining seaboard which belonged to the Pleistocene period as composed of Scotch firs and yews, with the spruce, the oak, the birch, and the alder, and showed that whilst the absence of the reindeer was significant, the presence of many species of mammals indicated that at this time Britain was united to the Continent. Though no trace of man has as yet been discovered in these primeval forests, his hour had come and rudely chipped implements of the river-drift hunter began to make their appearance in the late Pleistocene river deposits in Southern and Eastern England, and no difference can be detected in the *hâches* found in the caves of Cresswell in Derbyshire, and those of Thebes, of Palestine, and of France. This similarity, Professor Dawkins thinks, points not so much to the identity of the races of men that lived in these widely separated regions, as to a primeval condition of savagery from which mankind has emerged in the long ages which separate it from our own time.

#### SANITARY DEFECTS OF LONDON FLATS.

THE enormous rents paid by the occupiers of fashionable flats would, it might be imagined, suffice to ensure the use of the most recent improvements in sanitary appliances. Such, however, we regret to note, is not the case. In some cases the old and universally condemned container closet is still employed, and evidences of thorough ventilation in the drain-pipes are wanting. Defects of this description are more serious in flats than in ordinary houses, as the ventilation of the inhabited rooms is not so good. The houses are better built, the doors and windows close with more accuracy, and thus exclude accidental currents. Then to eight families there is but one front and back staircase and street door. Those constant and sweeping draughts of air due to the simultaneous opening of area and back-yard doors do not exist in these flats. Altogether therefore there is less accidental ventilation. The inhabitants of flats must rely for the renewal of air almost exclusively on the opening of the windows, and these, being of the ordinary type, are not easily managed in cold weather, and are consequently opened less frequently than is compatible with the removal of vitiated air. Further, the servants' bedrooms in some apartments have no windows at all, and in others are dependent for their ventilation on a window situated over the kitchen-sink, by the side of the kitchen-closet, and facing the bedroom door. The servants' quarters

are dark and unwholesome, so that altogether there is every reason to fear the advent of sewer-gas in these apartments would be more dangerous than usual. Fortunately the families who live in these flats do not often have children with them, so that the injurious effect of this state of affairs is less noticeable. Yet as the tendency is evidently to substitute flats for private houses, a natural consequence of the growth of London and the increased cost of land, we would urge that such sanitary defects should at once be remedied. The expense and trouble would be but slight, and in any case the enormous sum charged for the small accommodation given justifies the tenants in expecting that no pains will be spared to protect their health against the dangers of sewer-gas and difficult ventilation.

#### CIGARETTE SMOKING.

SCARCELY less injurious, in a subtle and generally unrecognised way, than the habit of taking "nips" of alcohol between meals, is the growing practice of smoking cigarettes incessantly. We have not a word to say against smoking at suitable times and in moderation, nor do our remarks at this moment apply to the use of cigars or pipes. It is against the habit of smoking cigarettes in large quantities, with the belief that these miniature doses of nicotine are innocuous, we desire to enter a protest. The truth is that, perhaps owing to the way the tobacco-leaf is shredded, coupled with the fact that it is brought into more direct relation with the mouth and air-passages than when it is smoked in a pipe or cigar, the effects produced on the nervous system by a free consumption of cigarettes are more marked and characteristic than those recognisable after recourse to other modes of smoking. A pulse-tracing made after the subject has smoked say a dozen cigarettes will, as a rule, be flatter and more indicative of depression than one taken after the smoking of cigars. It is no uncommon practice for young men who smoke cigarettes habitually to consume from eight to twelve in an hour, and to keep this up for four or five hours daily. The total quantity of tobacco used may not seem large, but beyond question the volume of smoke to which the breath organs of the smoker are exposed, and the characteristics of that smoke as regards the proportion of nicotine introduced into the system, combine to place the organism very fully under the influence of the tobacco. A considerable number of cases have been brought under our notice during the last few months, in which youths and young men who have not yet completed the full term of physical development have had their health seriously impaired by the practice of almost incessantly smoking cigarettes. It is well that the facts should be known, as the impression evidently prevails that any number of these little "whiffs" must needs be perfectly innocuous, whereas they often do infinite harm.

#### MORTALITY STATISTICS OF WATERING-PLACES.

AT this time of the year the competition between watering-places for the favour of the public takes various forms, and it speaks well for the growing intelligence of the visitors of seaside and holiday resorts that the local authorities of these resorts have recently shown so keen a susceptibility in the matter of death-rates. This anxiety to be able to provide a low death-rate is undoubtedly useful in exciting a local interest in sanitary conditions, upon which rates of mortality are more or less dependent. There is, however, a growing tendency to attach too much importance to death-rates for short periods of time in watering-places of small populations. The annual death-rate during three months in a population of a few thousand is of little real value as a test of sanitary condition, although it may be satisfactory to an intending visitor to know that the population among which he intends

temporarily to reside is not suffering from a high death-rate, or from a large proportion of zymotic fatality. One of the evils of this death-rate competition is a general tendency among sanitary authorities of watering-places to *correct* their death-rates, either by deducting the deaths of visitors, or by adding to the estimated population on the ground of the influx of visitors. Such corrections are of very doubtful expediency, as the means for making such corrections are of uncertain trustworthiness. It may be interesting to a watering-place like Scarborough to take, as it is proposed to do, a summer census, but much care should be exercised in applying such numbers to the calculation of a local death-rate. Summer visitors to Scarborough and similar watering-places rarely contribute to the local death-rate, whatever may be the effect of visitors upon the death-rates of such places as Hastings, Ventnor, and Bournemouth, which are favourite resorts of invalids.

#### PERMANGANATE OF POTASH IN SNAKE-BITE.

THE statements of De Lacerda on the treatment of snake-bite by permanganate of potash have led Mr. Vincent Richards, formerly a member of the Indian Snake-poison Commission, to undertake a series of researches on the efficacy of the treatment in cobra poisoning. The details of the experiments, which have been lately published, do not corroborate the assertions of the Brazilian physician. Nevertheless, they show that the permanganate, while it does not possess all the power which has been claimed for it, is far from useless, and the results cannot be regarded as a refutation of De Lacerda's statements, since the snake poison investigated was not the same. The cobra virus is certainly destroyed by contact with the permanganate out of the body. In dogs, no appreciable symptoms followed the hypodermic or intravenous injection of a watery solution of from two to seven centigrammes of cobra poison, when previously mixed with from one to three decigrammes of permanganate of potash; although, under ordinary circumstances, such a quantity of the virus is more than sufficient to produce fatal results. When a similar dose of the poison was injected beneath the skin of a dog, and immediately, or at an interval of not more than four minutes, a watery solution of from one to six decigrammes of permanganate of potash was injected into the same part, no appreciable symptoms of cobra poisoning could be observed. If, however, glycerine was used to dissolve the cobra poison instead of water, the permanganate appeared to have no influence on the intensity of the virus. It will be remembered that De Lacerda claimed that permanganate is perfectly effectual, even after the constitutional effects of the poison have commenced. Mr. Richards does not find this to be true of the cobra poison. When symptoms had developed, the injection of the permanganate—hypodermic or intravenous, or both—failed to exercise any influence on the symptoms. Moreover, it possesses no prophylactic powers, since death followed the hypodermic injection of three and a half centigrammes of cobra poison, in watery solution, in the case of a dog, beneath the skin of which eight decigrammes of permanganate had been injected a few hours previously. Thus it appears to be absolutely necessary that the permanganate, to be effectual, should come into actual contact with the cobra poison. The permanganate cannot therefore be regarded as an antidote in the proper sense of the word. It is, nevertheless, an agent of considerable value. Up to the present time, the only really effectual means of treating cobra poison has been the ligature followed by amputation. But in the permanganate we have the means of neutralising the poison while it is in the tissues, although we cannot influence it after it has got into the blood. In the tissues, it is necessary that the permanganate should come

into actual and complete contact with the cobra poison. Sloughing is an almost invariable consequence of the injection. Two experiments may be mentioned which clearly illustrate the value of this treatment. The poison was removed from the glands of a cobra, and one-half was injected into a dog weighing fifty pounds, and the other half into another dog weighing only thirty-two pounds. No remedy was applied to the former, and the animal died in six hours and three-quarters. In the second dog, permanganate was injected five minutes after the introduction of the poison, and although the animal was smaller and less strong than the other, it exhibited no symptoms. Again, two dogs were injected, each with two centigrammes of cobra poison. To one a supposed antidote, which had been received from Africa, was administered almost immediately after the injection, but the animal died in less than six hours. In the other case, five minutes after the injection, a catgut ligature was applied, and thirteen minutes later (eighteen minutes after the injection) a solution of permanganate was sent into the part, and the animal showed no symptoms of poisoning. Failure is generally due to a defective application of the ligature, or insufficient injection. Sometimes, however, the intervals are too long; or the dose of poison too large. The best result was obtained in a case in which a quantity of poison was injected into a dog sufficient to kill it in five or six hours, and the ligature was applied five minutes after, followed by the injection of the permanganate of potash twenty minutes later—twenty-five minutes after the injection of the poison. The animal did not exhibit a single symptom of snake-bite. It sometimes happens, from the ligature or the injection being insufficient, that some of the poison will be absorbed, and serious symptoms occur, from which the animal may or may not recover, but which are less rapid than without the injection. A series of experiments made to determine the best strength and quantity of the permanganate solution showed that while a 2 per cent. solution may answer, it is safer to employ a 5 per cent. solution. This must be thoroughly injected, two or three drachms being sent into the part, which should be well pressed with the fingers. This is the estimate for the usual quantity injected by the cobra in its bite, a quantity which usually causes the death of a man in five or six hours. A tight ligature should of course be applied immediately after the bite, and should not be removed until some minutes after the injection. Mr. Richards throws out the suggestion that the injection of the permanganate deserves a trial in bites of rabid animals, the virus of which would probably be destroyed by it. The suggestion certainly deserves attention at the hands of those who are engaged in experiments upon the subject.

#### THE DISINFECTING OF DUSTBINS.

DURING hot weather it is more especially necessary to watch that the removal of dust does not occasion a dangerous nuisance. Theoretically the dustbin of each private house should not contain any organic matter liable to rapid decomposition. Vegetable refuse, even fish-bones, should be burnt behind the kitchen fire, and the dustbin, holding only dust, would not, particularly if emptied at short and regular intervals, give rise to any inconvenience. Practically, however, vegetable and animal matter, together with a considerable amount of moisture, are not only often thrown in the ash receptacles, but kept there many days and even weeks beyond the prescribed limit of time. When finally the emptying takes place there is an upheaval of fermenting and rotten matter, that throws off gases of a highly dangerous character. In a street near Covent-garden, we recently witnessed an operation of this nature. The stench in its foulness was beyond description, and travelled a distance of more than fifty yards up the street and reached the top floors of the houses. On

inquiry it was found that no effort whatever was made to abate this nuisance; and therefore we would urge that, in future, scavengers should always carry with them a quantity of disinfectants. If dustbins are badly kept the disinfectant should during the emptying be mingled with the contents in sufficient quantities to prevent a nuisance; and in such cases it would be only fair to charge the inhabitants of the house with the extra cost their carelessness had necessitated. It should be remembered also that the unpleasantness and risk are not limited to the house whence the filth is removed. The scavengers have to travel sometimes several miles with their heavy carts jolting their foul contents, and emitting poisonous exhalations through thickly populated streets. Then when finally the dustyard is reached, the danger is not over. Here a number of poor women sift the dust carefully, to extract therefrom anything that may have some value, such as small coal, paper, old shoes, and even a stray spoon. Again we urge that all these operations should not be allowed unless their danger is mitigated by the extensive use of disinfectants; while, on the other hand, stronger pressure should be brought to bear on householders who allow their dustbins to become a nucleus of disease.

#### PORK-MEASLE IN MAN.

M. TROISIER exhibited lately to the members of the Paris Hospital Medical Society a man thirty-six years old, a Parisian, who for a year past had noticed small swellings arise on the cheek, arms, legs, and abdominal wall. These swellings proved to be due to cysticerci, and, curiously enough, the patient had passed a *tania solium* whilst bearing these larvæ in his body. M. Troisier suggested two hypothetical explanations of the coincidence: either that the man had swallowed the ova of his own tapeworm, or that tapeworm and cysticerci were derived from the same external source. He asked what treatment should be followed to rid the patient of his disease. No one could dream of removing them one by one, but some such simple method as puncture with the hypodermic syringe might suffice to kill them. Many similar cases are referred to by Lancereaux in his work on Pathological Anatomy, although they are not so frequent as the occurrence of solitary cysticerci in organs. Lancereaux gives a figure showing numerous subcutaneous cysts in a woman, and among other facts quotes the statement of Rudolphin to the effect that in his time at Berlin cysticerci were found in one out of every fifty post-mortem examinations, occurring most often in the gluteal, psoas, iliacus, and vasti muscles, and more rarely in the brain. Bonhomme, in one case, calculated that there were as many as two thousand lodged in the subcutaneous, subfacial, and intermuscular connective tissue.

#### UNCERTIFIED DEATHS AT LEEDS.

THE *Leeds Mercury* of Aug. 24th reports some very important observations of the Borough Coroner on the number of uncertified deaths in Leeds which have to be submitted to investigation by a coroner. The coroner regards this as a very serious matter, for which he blames the system of cheap dispensaries. Last week five cases came from one surgery. It was not right, the coroner said, for a medical man to open a number of branches and fill them with unqualified assistants who could not certify. We regret that the coroner should have the trouble of investigating the cases that end fatally under such a system. But he must be comforted by reflecting that he is exposing a great evil, which has been lately more thoroughly exposed in London. The poor are partly themselves to blame. They are thoughtless about the remuneration of medical men, and think to get medical attendance for grave illnesses for sums they would be ashamed to give their publicans for a week's beer.

#### SCOTTISH UNIVERSITY COMMISSION.

DURING the earlier part of the past session of Parliament high hopes were indulged by those interested in the Scottish Universities that a strong Executive Commission would be named having power, not only to supplement the inquiries of the late Commission, but to order such reforms as are now necessary. The Universities of Edinburgh, St. Andrews, and Aberdeen have shown a strong desire for immediate action; indeed, without this the very existence of St. Andrews, the oldest of the northern Universities, as an efficient teaching body, seems questionable. Glasgow opposes the action of her sister Universities, and would prefer that such changes as are necessary should be instituted by her own authorities. As regards the curricula, perhaps the most important change sought is that by which several routes would be allowed towards graduation in Arts. This would materially affect the medical curriculum also, as the M.A. who chose to graduate in natural science would not require a second examination in those subjects prior to graduation in medicine, and this change will probably raise the whole question as to the position which chemistry, zoology, and botany should occupy in medical education. A large body of opinion in Scotland supports the proposal to place these subjects in the preliminary examination, while perhaps a more influential section would wish to see other subjects added to that examination, or the present subjects made so severe as to give a better guarantee of a good general education, and that the first professional examination should be in pure science, including physics, afterwards leaving the four years for purely medical study. It is just possible that the year's delay may be most useful, so far as medical education is concerned, as the present period of change brings daily into greater prominence the practical and demonstrative element in teaching. The necessity of arranging for the appointment and remuneration of a sufficient number of assistants to the professors will be more fully recognised as the new system becomes more permanent, and other questions which we hear mooted, such as the status of extra-mural lecturers and their more full recognition by the University authorities, will have time for consideration by the interested parties, and perhaps for informal debate by opposing interests. The Government are pledged to take early action, and next session is almost certain to see the appointment of a strong Commission.

#### VINDICATION OF MEDICAL MEN IN SOUTH AFRICA.

THE *Port Elizabeth Telegraph* does a service to the public, more even than to the profession, in holding up to contempt the finding of a court in which Dr. Sharpe, of Jagersfontein, was the plaintiff against one Salmon, a druggist, who declared that three grains and a half of chlorate of potash was a poisonous dose and the cause of the death of a child. The court found that Salmon had not spoken in malice and, secondly, that the doctor, being in arrear with his licence fee for that year, had no *locus standi* in courts of justice. This is a most unjust and inadequate verdict on a charge the most absurd that was ever made by a chemist. The sooner some pharmaceutical society is established to test the knowledge of chemists the better.

#### THE VACCINATION INQUIRY AT NORWICH.

THE investigation by Mr. Henley and Dr. Airy into the deaths at Norwich, alleged to have resulted from vaccination, is not yet concluded. We must therefore defer remarks on the case, save the expression of the hope that the protracted nature of the inquiry may be taken as a guarantee that it will be full and complete.

## MATTERS AT THE CAPE.

THE *Port Elizabeth Telegraph* seems to take a sensible view of the advantages of medical coronerships, and supports various towns in the eastern province which are agitating for properly constituted Coroners' Courts. We cannot imagine a more important object than this for such towns. The question of small-pox, also, is a burning one in the colony. If wisdom is displayed by the authorities and the population, it should be possible to restrict its ravages. The *Times* reports the spread of the disease in Cape Town. The immediate revaccination of every person above seven years of age in an infected house, the vaccination of all unvaccinated persons, and the revaccination of all unrevaccinated adults, would make short work of the epidemic. Practitioners will doubtless make every effort to practise vaccination from arm to arm in well-selected cases, so that by its thoroughness it may be appreciated by the community, which never appreciates vaccination excepting when face to face with small-pox. The *Telegraph* touches on another question not without interest in a medical respect. It alleges that farmers are neglecting the cultivation of sheep under the temptation of the high price of ostrich feathers. More attention, too, is paid to the wool than to the weight of the carcase of the sheep. Under these circumstances, the price of the daily joint of the working man is assuming such proportions as will render butchers' meat as great a luxury to him in South African colonies as to the Dorsetshire labourer. The sooner this is realised the better.

## STRANGULATED HERNIA: WOUND OF INTESTINE.

A WOMAN, aged thirty-five, who had for many years had a right inguinal hernia only imperfectly kept up with trusses, and who three months previously had had an abscess over the hernial sac, was admitted into the Necker Hospital under M. Trélat with all the symptoms of strangulation of the hernia. As taxis had already been tried, M. Trélat had her at once anaesthetised, and, after a further attempt at taxis, operated. On opening the sac he found the intestine bound to the sac by old adhesions. He proceeded to dissect through these adhesions, and while so doing the gut ruptured. The dissection was proceeded with, and then the wound in the intestine was closed with seven interrupted sutures, and, after careful cleansing of the parts, the gut was returned, the sac excised, and the wound closed by deep and superficial sutures. Next day the patient passed a motion. The wound healed by first intention, the drainage-tube was removed on the fourth day, and the patient recovered without any complication. This case is very encouraging, for the congested state of the intestinal walls was not favourable to rapid healing of a wound in it or to tolerance of sutures.

## THE SANITARY STATE OF MARLOW.

DURING the recent proceedings of the Wycombe rural sanitary authority the condition of Marlow came under consideration. A number of conditions, which may be summed up in the words of one of the speakers as "dirt, filth, and overcrowding," were specified, and one member of the authority pointed out that visitors to this favourite riverside town had grounds for reporting in a public paper that the sewage of the place was running down the streets. The inspector of nuisances warned the authority that if they once touched the question of drainage it would be a very serious thing, and when the chairman inquired where the overflow from a large cesspool went to, he first supplied an answer to his own question by explaining that it went into some one's well, and then elicited a further explanation from the inspector of nuisances to the effect

that the town lies on a gravelly soil which is practically honeycombed with wells and cesspools. Under these circumstances it would be exceedingly unwise for the sanitary authority to postpone for any length of time the adoption of necessary remedial measures.

## SEWAGE RESERVOIRS ON THE THAMES.

THE Metropolitan Board of Works have shown wisdom as well as good taste in their decision to defer the extension of their sewage reservoirs at Barking and Crossness until the Royal Commission now sitting has finished its labours. The Commission has adjourned until October 24th, and in the meantime an immense mass of evidence, practical and scientific, is accumulating. London owes so much to the Metropolitan Board that it is regrettable to find that body on the present occasion in opposition to what we take to be the general feeling of Londoners.

## HOSPITAL SATURDAY.

THE present Saturday (September 2nd) is the day for taking up the Hospital Saturday Fund. We heartily wish it success. It is essentially an appeal to the working classes of the metropolis on behalf of institutions in which, on the occurrence of grave accident or disease, they are treated by the best physicians and surgeons in London. Hitherto the result has not been at all adequate to the means of those to whom the appeal is made.

## SPONTANEOUS EXPULSION OF A VESICAL CALCULUS.

M. MOUCHET recently showed to the Société de Chirurgie of Paris a phosphatic calculus measuring 7 cm. by 6 cm. by 5 cm. This calculus had been lodged for a long time at the neck of the bladder of a woman, seventy-two years of age, and had been mistaken for a malignant tumour. During a severe attack of pain it was expelled into the vagina. The patient recovered with only a small urethro-vaginal fistula.

DR. BLAXALL, R.N., Medical Inspector to the Local Government Board, is actively pursuing his inquiry as to the sanitary circumstances and surroundings of emigrants passing through this country to their several ports of departure for America and elsewhere. The question of infectious disease amongst them, either when the symptoms are already manifested or during the period of latency, is engaging special attention with a view to the adoption of remedial measures to stay the spread of infection by isolation and otherwise. Captain Wilson, representing the Board of Trade, is associated with Dr. Blaxall in the inquiry, and the two commissioners have recently been engaged in eliciting the facts relating to the port of Liverpool.

MEDICAL practitioners in England complain, and justly, of the inadequate remuneration they often receive for the inconvenience to which they are put and the time lost in giving evidence at inquests. But their brethren at the antipodes are in worse case, since it appears they are compelled in some instances to travel 200 miles on horseback to bear sworn testimony to the cause of death, receiving as fees for the journey and full professional expenses the sum of £7 13s.!

ASSISTANT-SURGEON C. CRANE, U.S.A., so long and ably connected with the office of the Surgeon-General, at Washington, D.C., and occupying for many years the position of Assistant-Surgeon-General, has been appointed by the President, Surgeon-General to the United States Army, in succession to Dr. J. K. Barnes.

WE have received from Mr. Stanford, of Charing-cross, two maps, one showing the Nile Delta, with plans of Port Said, Ismailia, Suez, and Cairo, also the Canal and Cape Route to India, Australia, &c.; the other presenting on a large scale the seat of military operations in Lower Egypt. Both maps are characterised by the excellence for which the productions of the above firm are distinguished.

CHOLERA is reported to be increasing at Manilla, Luzon, one of the Philippine Isles. The Spanish Government have adopted stringent precautions against importation of the disease. The epidemic is raging also in Japan. Despatches received at Madrid state that of 775 cases at Yokohama, 572 proved fatal.

THE typhoid epidemic at Bangor exhibits at present but faint indications of abatement. Attention has been directed to the water-supply, and the water of the river has been temporarily diverted from the filter bed of the reservoir. All the schools continue closed.

DR. A. W. SMYTH has received from President Arthur the appointment of Superintendent of the New Orleans Mint. This selection would seem to imply that Dr. Smyth has obtained as a politician a distinction second only to that he is acknowledged to have gained as a surgeon.

WE have information as to the prevalence of diphtheria in and about Midhurst in Sussex. According to the last quarterly return of the Registrar-General, two fatal cases were recorded in the Midhurst subdistrict during the quarter ending June 30th.

THE French Minister of Agriculture has placed at the disposal of M. Pasteur a further sum of fifty thousand francs, for the purpose of continuing his researches in connexion with the contagious diseases of animals.

MR. HENRY BUTLER, F.R.C.S. Eng., and E. L. CROWTHER, M.D. Aber., L.R.C.P. Ed., have been re-elected Members of Parliament, Hobart, Tasmania.

## Public Health and Poor Law.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Kensington.*—According to Dr. Dudfield's annual report for 1881 the death-rate for the parish was only 16·6 per 1000 living. This is the lowest rate recorded, but the parish was less favourably distinguished by having also an exceptionally low birth-rate—namely, 26·9 per 1000, or 7·8 per 1000 below that of the metropolis generally, and this notwithstanding the fact that there was a high marriage-rate, which reached 21·6 per 1000, as opposed to 18 per 1000 in the metropolis generally. The deaths under one year of age amounted to 14·6 per cent. on the registered births, as compared with 15·6 per cent. in the 19 large towns and cities. The year 1881 was memorable in Kensington, as in the metropolis generally, for the epidemic of small-pox which, commencing towards the end of 1880, continued with varying severity throughout the year. In all, 369 cases were heard of in Kensington. Of this number 300 were treated in hospital with a mortality of 14 per cent., and 69 remained at home with a mortality of 19 per cent. Concealed cases may, however, vitiate the value of the rate as regards the home cases. Most of the patients who went to hospital

were removed to the Fulham Hospital, which received 1914 cases, Kensington contributing 275 patients. The history of the legal proceedings, which ended in the issue by the Court of Common Pleas of an order limiting the use of the hospital to patients residing within a radius of one mile of the building, is entered into; and the circumstances which led to Dr. Thorne Thorne's and Mr. Power's report on infectious hospitals, and on the influence of the Fulham Hospital, are also referred to; the delay in the issue of those reports being explained as due to the circumstance that they are in the hands of the Royal Commission on Infectious Hospitals. Pending the distribution of the Commissioner's report, Dr. Dudfield defers the discussion of several points relating to the late epidemic. He, however, adverts to the fact that during its progress the rest of the kingdom remained all but free from small-pox, whereas during former epidemics many of the large towns suffered even more severely than the metropolis; and he attributes the marked decline in small-pox mortality in the nineteen large towns coming next to London to the fact that since 1875 they have been in charge of medical officers of health, and that there has in each of them been a unity of sanitary administration; whereas, on the other hand, London, with its divided sanitary control, retains an unenviable pre-eminence as regards this mortality. Dr. Dudfield has all along been an ardent advocate for the compulsory notification of infectious diseases, and he would welcome a general statute dealing with this subject, whether the duty of notifying devolved on the medical practitioner or on the householder. He, however, personally favours the former alternative, and feels convinced that, whatever is done as a first step, the intimation must in the long run be made by members of the medical profession. As to this subject, the terms of the special report of the Committee of the House of Commons appointed to deal with private Bills affecting police and sanitary regulations are extensively quoted and commented on. Many other subjects, including a general review of the various sanitary circumstances of London, such as its water-supply, &c., which affect Kensington, as also an account of the action taken to prevent the spread of disease and to secure the abatement of nuisances, are dealt with in Dr. Dudfield's report, which forms a comprehensive summary of all the conditions affecting health in the district which is under his control as medical officer of health.

*Worley.*—Dr. Samuel Drew, in retiring from the post of medical officer of health to the No. 1 District of the Worley Union, points out to the rural sanitary authority that whereas in the two years following on his appointment in 1873 the death-rate amounted to 24 per 1000 persons living, it had during the past two years only reached 17 per 1000. This diminution in the death-rate, which led to an annual saving of 119 lives in the district, was, in his opinion, in great part due to the sanitary improvements which had been adopted, and to the effective administration which had been carried out.

*Glasgow.*—Mr. Kenneth Macleod, the Sanitary Inspector for the City of Glasgow, presents a separate report, which gives evidence of the excellent sanitary work which is carried on under Dr. Russell's supervision. From this report it appears that when any drain nuisance is suspected the smoke test is applied to the drains of the house in question, and a report of all the leakages and defects which are detected is presented to the house-owner, together with details as to the remedial measures which are necessary. All this is done without any charge, and it is not surprising to find that the public are rapidly learning to appreciate the action of the sanitary authority in this respect. With a view to the more effectual arrest of infectious diseases a special washhouse for infected linen and other articles was established in the city in 1864. In 1871 more commodious premises were procured, but the rapidly increasing demand on its limited resources has led to a determination to erect new buildings on a much larger scale. In 1865 the total number of articles disinfected and washed amounted to 29,489, whereas in 1881 the number had reached 206,953. And it is shown that this large increase is by no means due to an increase in the number of fever patients, but rather to the fact that the work of cleansing and disinfecting is so well carried out that the public forward to the establishment many articles with which they formerly did not trust the authority. Thus in the first year of its history the washhouse received at the rate of four articles from each fever patient for whose purposes the establishment was used; whereas in 1880 the rate had increased to thirty articles per

patient. The health committee, being desirous, above all things, to protect the citizens from the risk of infection, carry out all this work free of cost to the sick whose articles are dealt with.

*Dublin.*—During the four weeks ending August 1st, the deaths within the metropolitan registration area were in the ratio of 19·17 per 1000. The death-rate during July was 1·22 lower than it was in the preceding month; while the mortality caused by diarrhoea and dysentery was somewhat, but not excessively, high. There were very few cases of any of the other zymotic diseases. If last month is contrasted with the corresponding period during the last ten years, it will be found that the zymotic death-rate was little more than one-third of the average rate. A very large amount of fish in a state of semi-decomposition was detected during the month and destroyed.

#### ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD FOR IRELAND.

We learn from this report, which is of a highly interesting character, that the average daily number of persons receiving relief in workhouses during the year was 52,772, and out-door relief 60,196, which, compared with similar returns for the previous year (53,796 and 60,833) show a decrease of 1024 and 687 respectively. During the year 56,027 persons were under treatment in the workhouses for various affections, including 7222 cases of fever, or other contagious disease, with a mortality of 11,860. A decrease of 6604 took place in the total number admitted sick to workhouses during the year, also in the number of fever cases, and in the mortality of those admitted. Last year 632,493 new cases were attended by dispensary medical officers, which included 187,562 visiting tickets, and 113,557 people were vaccinated or revaccinated during the same period, being a decrease of 34,271 as contrasted with the previous year. Sixty-four deaths took place in workhouses from small-pox; and there was a considerable decline in the number of fever cases attended by dispensary medical officers, the numbers being 9713, against 11,211 in 1880. The total expenditure of poor-rates for all purposes—viz., relief, medical relief, burial grounds, registration of births, deaths, and marriages, sanitary measures, expenses under Superannuation Act, &c., was £1,251,617, being an increase in the total expenditure of £64,369. The current sanitary expenditure for the year was £48,918, against £51,927 in the year preceding.

#### VITAL STATISTICS.

##### HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns, 5600 births and 3680 deaths were registered during the week ending the 26th ult. The annual death-rate in these towns, which had slowly increased in the five preceding weeks from 19·0 to 23·4, declined again last week to 22·7. The lowest rates in these towns were 13·7 in Derby, 16·4 in Bristol, 18·2 in Halifax, and 18·8 in London. The rates in the other towns ranged upwards to 29·5 in Birmingham, 31·3 in Wolverhampton, 32·0 in Salford, and 34·5 in Hull. The deaths referred to the principal zymotic diseases in the twenty-eight towns further rose last week to 1058, and showed a further increase of 68 upon recent weekly numbers; 751 resulted from diarrhoea, 95 from whooping-cough, 75 from scarlet fever, 53 from "fever," 50 from measles, 31 from diphtheria, and only 3 from small-pox. The lowest death-rates from these diseases last week occurred in Derby and Bristol, and the highest in Nottingham and Hull. Diarrhoea showed a further general increase of mortality, and caused the highest death-rates in Wolverhampton, Nottingham, and Hull; whooping-cough caused the highest death-rates in Oldham and Plymouth; scarlet fever in Salford, Oldham, and Plymouth; measles in Huddersfield; and "fever" in Blackburn and Preston. The 31 deaths from diphtheria in the twenty-eight towns included 18 in London, 3 in Birmingham, and two both in Manchester and Leeds. Of the three deaths from small-pox, two occurred in Newcastle-upon-Tyne and one in London. The number of small-pox patients in the metropolitan asylum hospitals, which had declined in the seventeen preceding weeks from 350 to 111, were 114 on Saturday last; and 32 new cases of small-pox were admitted to these hospitals during last week, against 19 and 18 in the two preceding weeks. The deaths referred to diseases of the respiratory organs in

London, which had been 223 and 197 in the two preceding weeks, were 199 last week, and exceeded the weekly average by 41. The causes of 83, or 2·3 per cent., of the deaths in the twenty-eight towns last week were not certified either by a medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Birmingham, Nottingham, Derby, and Blackburn; whereas the proportions of uncertified deaths were largest in Wolverhampton, Bolton, and Cardiff.

##### HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had been 20·1 and 20·7 in the two preceding weeks, was 20·0 in the week ending the 26th ult.; it was 2·7 below the mean rate last week in the twenty-eight large English towns. The deaths referred to the principal zymotic diseases in these Scotch towns were 136 last week, and showed a slight further increase upon recent weekly numbers; they included 81 from diarrhoea, 12 from scarlet fever, 12 from diphtheria, 12 from "fever," 11 from whooping-cough, 8 from measles, and not one from small-pox. The death-rate from these principal zymotic diseases averaged 5·8 per 1000, and was 0·7 below the mean rate from the same diseases in the twenty-eight large English towns. The 81 deaths attributed to diarrhoea showed a further considerable increase upon recent weekly numbers, and were more than three times as numerous as in the corresponding week of last year, when only 25 were recorded; the fatality of this disease was considerably higher last week in the English than in the Scotch towns. Diarrhoea was most fatal last week in Greenock, Edinburgh, and Dundee. The 12 deaths from scarlet fever showed a slight decline from the numbers returned in recent weeks, and included 5 in Glasgow and 3 in Paisley. The fatal cases of diphtheria, which had been 10, 13, and 17 in the three preceding weeks, declined last week to 12, and included 9 in Glasgow and 2 in Greenock. The deaths referred to "fever," which in the two previous weeks had been 8 and 15, also declined to 12, of which 5 were returned in Glasgow, and 2 both in Paisley and Perth. The 11 deaths from whooping-cough were 4 less than those returned in the preceding week, and included 5 in Glasgow and 3 in Aberdeen. The 8 fatal cases of measles corresponded with the number in the previous week; 4 were returned in Dundee, 2 in Glasgow, and 2 in Leith. The deaths referred to acute diseases of the lungs in the eight towns, which had been 71 and 73 in the two preceding weeks, declined to 60 last week, and exceeded by 8 the number attributed to the same diseases in the corresponding week of last year.

##### HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 23·5 and 20·1 per 1000 in the two preceding weeks, rose again to 23·6 in the week ending the 26th ult. During the first eight weeks of the current quarter the death-rate in the city averaged 21·3 per 1000, against 18·6 in London and 17·9 in Edinburgh. The 159 deaths in Dublin last week showed an increase of 25 upon the low number in the previous week; they included 16 which were referred to diarrhoea, 6 to "fever," 4 to whooping-cough, 1 to scarlet fever, and not one either to small-pox, measles, or diphtheria. Thus 27 deaths resulted from these principal zymotic diseases, against 15 in each of the two previous weeks; these were equal to an annual rate of 4·4 per 1000, while the rate from the same diseases was 4·0 in London and 4·5 in Edinburgh. The fatal cases of diarrhoea, which had slowly increased from 5 to 10 in the four preceding weeks, further rose to 16 last week, and exceeded the number returned in any previous week of the year. The six deaths referred to "fever" (enteric, typhus, or simple), showed an increase of four upon the number in the previous week. The deaths from whooping-cough, which had been but three since the end of March, rose to four last week. The deaths both of infants and of elderly persons showed a considerable increase upon the numbers in the previous week. The causes of 22, or nearly 14 per cent., of the deaths registered during the week were uncertified.

##### THE DECLINE OF THE BIRTH-RATE IN FRANCE.

A recent number of the Journal of the French Statistical Society contains an article calling attention to the serious aspect of the vital statistics of France. The official statistics

for the year 1880 have not long been issued, and they afford good ground for the grave consideration of patriotic Frenchmen. The marriage-rate, which was equal to 8.85 per 1000 of the population in 1873, has since steadily declined, and was but 7.47 in 1880. This decrease is partly attributed to the effect of the Franco-German war, which caused an increase of the marriage-rate in 1873-5, in reaction from the reduction of the rate while the war lasted; moreover, the loss of young men during the war is still said to affect the marriage-rate. Partly, probably, in sympathy with the steady decline in the marriage-rate, the birth-rate has shown a coincident decrease. The birth-rate in France, which in 1873 did not exceed 26.1 per 1000, has since further declined, and in 1880 it was but 24.7. If we exclude 1871, when the direct effect of the war caused the rate to fall exceptionally low, the proportion of births to the population has not been so low as it was in 1880. The Journal of the Statistical Society pertinently remarks that in no other European State that publishes such statistics is the birth-rate so low as in France, and that the rate in the German Empire in 1880 averaged no less than 39.1, or 60 per cent. higher than the French rate. The French death-rate shows no decline to balance the decrease of births in the population. The rate in 1880 was 23.0 per 1000, and slightly higher than in any year since 1875; the mean rate in the two periods of four years ending 1876 and 1880 was almost identical. It is pointed out, however, that the French death-rate compares favourably with that prevailing in any other European nation, except in England and in the northern Scandinavian countries. This fact is in error partly attributed by the Statistical Society's Journal to the low birth-rate in France. In English populations, however, a low birth-rate is evidence of an age-distribution of the population which produces an abnormally high death-rate. The small proportion of young adults in the French population, and the relatively larger proportion of elderly persons, partly account for the excess in the death-rate. As the inevitable result of the decrease in the birth-rate, and the steadily maintained death-rate, the natural increase of the population by excess of births over deaths, which was 172,946 in 1874, fell to 61,846, or considerably less than half, in 1880. The natural increase of population, according to the figures in 1880, would have caused the population to double itself in 145 years. In accordance with the figures in 1880, however, it would take no fewer than 433 years for the French population to double itself. This want of elasticity in the French population is more remarkable when compared with the rapid increase in England and Germany.

#### TYPHOID IN PARIS.

At the meeting on August 11th of the Paris Hospitals Medical Society, M. Decestral read the report upon prevalent diseases for the second quarter of the year. It showed a much higher mortality than in the corresponding period of previous years. Typhoid fever and diphtheria have prevailed to an extreme degree, and pulmonary diseases have been most numerous and severe. In the hospitals there were 378 cases of diphtheria, as against 267 (in 1881); in the town 728 instead of 523, the mortality reaching the enormous figure of 70 per cent. In the month of June typhoid fever showed a marked increase—viz., 452 cases admitted into the hospitals; in the town 192 deaths, instead of 97 in the previous year. M. Dujardin-Beaumetz declared that he had never seen so much typhoid fever as at present. In the St. Antoine Hospital there were thirty cases in one ward. M.M. Montard Martin and Troisième stated that the pressure was so great at the Hôtel Dieu that an annex had just been opened to receive patients. Later accounts from Paris fully bear out these statements, especially as regards typhoid fever, which is remarkably prevalent.

#### THE SERVICES.

Surgeon-Major Alfred Clarke has been appointed to the medical charge of the Royal Military College, Sandhurst, vice Deputy Surgeon-General Thomas Frazer, M.D. retired. Surgeon-Major William Johnston succeeds Dr. Clarke as Staff Officer of the Army Hospital Corps and Assistant in the Sanitary branch of the War Office, Whitehall-yard.

Surgeon-Major W. Wilson, M.D., has embarked on board the P. & O. steamer *Siam*, in medical charge of the troops

proceeding to Egypt. The *Siam* left the Albert Dock on the 30th ult.

Surgeon-Major Wm. Sly has left England for Gibraltar.

Surgeon-Major Barker has been ordered from Dover to Aldershot to organise the 3rd Bearer Company for service, if required, in Egypt.

Surgeon-Major Melladew, Royal Horse Guards, has been detailed to accompany the detachment of Household Cavalry leaving the Albert Docks on Saturday in the *Persian Monarch* for Ismailia.

Surgeon-Major T. Wood proceeds to Egypt in medical charge of the troops in H.M.S. *Tyne*.

Surgeon-Major W. K. Cumming, Army Medical Department, has been granted leave of absence from India, pending retirement from the service.

Surgeon-Major John Berry White, Indian Medical Department, has retired from the service.

The Queen has approved the retirement of Surgeon-Major Thomas Miller, M.D., and Surgeon-Major Malcolm Munro Mackenzie, of the Bombay Army.

ARMY MEDICAL DEPARTMENT.—The undermentioned Surgeons on probation to be Surgeons:—Sinclair Westcott, Hayward Reader Whitehead, Bruce Morland Skinner, Charles Richard Bartlett, John Dennis Thorpe Reckitt, Thomas Alfred Parry Marsh, Roger Kirkpatrick, M.B., Alexander Charles Archibald Alexander, Harry Strickland McGill, Augustus Alexander Pechell, M.B., Charles Robert Tyrrell, James Hickman, Wilfred Burrell Thomson, Herbert Edward Deane.

BREVET.—Surgeon-Major Edric Selous, of the Bengal Army, to be Brigade-Surgeon.

RIFLE VOLUNTEERS.—1st Cambridgeshire: Surgeon Alfred Nicholas Jones is granted the honorary rank of Surgeon-Major.—1st Durham: Honorary Assistant-Surgeon Samuel Winn Broadbent to be Surgeon.—1st Kent: Surgeon Blackall Marsack resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the corps on his retirement.—3rd Monmouthshire: Acting Surgeon Charles Bent Ball, M.D., resigns his appointment.

ADMIRALTY.—The following appointments have been made:—Surgeon William Edw. Bennett, to the *Audacious*; Surgeon Edmund D. Maddick, additional, to the *Duke of Wellington*; Staff Surgeon Richard S. P. Griffiths, to the *Bernarda*, Dockyard, vice Power; Staff Surgeon William T. Power, to the *Cronos*, vice Griffiths; and Surgeon John Price, to the *Indus*, vice Twigg; Fleet Surgeon John Breaky, to the *Duncan* (additional); Fleet Surgeon Thomas Smith Burnett, to the *Audacious*; Fleet Surgeon Stephen Sweetnam, to the *Valiant*, vice Thomas S. Burnett.

#### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

FROM the annual statement of the receipts and expenditure of this College during the official year from midsummer-day, 1881, to midsummer-day, 1882, it appears that the income of the College from all sources amounted to £18,578 2s. 11d., of which sum £15,653 3s. was received by examination fees alone—viz.: preliminary examination, £996; primary and pass examination membership, £13,191 3s.; primary and pass examination fellowship, £1172; dental examination, £294. Rent of chambers and house property in Lincoln's-inn-fields produced £1523 14s. 6d.; dividends on stock, £1097 4s.; incidental receipts, £129 15s. 2d.; and receipts from trust funds, £174 6s. 3d. Total, £18,578 2s. 11d. The expenditure over the same period, including an investment of £1073 15s., was £17,272 2s. 5d., and may be divided as follows:—"Fees to members of Council, £213 3s.; College of Preceptors preliminary examination, £315 9s. 6d.; Board of Examiners in anatomy and physiology, Court of Examiners, and working expenses at membership and fellowship examinations, £6432 6s.; examiners in medicine, £292 4s.; examiners in midwifery, £96 16s.; examiners in dental surgery, £95 17s.; diploma stamps, £390. College department: salaries and wages, stationery, printing, advertisements, postage-stamps, fuel and light, &c., £2916 17s. 3d. Museum department: salaries, wages, and pensions, lectures, specimens, spirit, glasses and bottle, &c., £2135 6s. Library department: salary and wages, purchases, and

binding books, &c., £771 9s. Taxes, rates, and insurance of College buildings, £1135 10s. 8d.; alterations, repairs, and painting, £559 16s. 7d. Extraordinary expenditure: conversazione to the members of the International Medical Congress, £278 10s. 8d. Trust funds, £118 5s. 5d.; investment, £1073 15s.; miscellaneous items, £445 16s. 4d. Total, £17,272 2s. 5d.

## NOTES ON SOME KNOWN MINERAL SPRINGS IN MADAGASCAR.

MR. G. W. PARKER, L.R.C.P. Lond., M.R.C.S., Physician and Surgeon to the Queen of Madagascar, has favoured us with the following particulars of the mineral springs of the island.

Since extinct volcanoes are very numerous in some parts of the island of Madagascar we should naturally expect to find springs, either hot or cold, which might be useful in the cure of diseases. And such is the case, although the capabilities of this large island, in this respect, are almost unexplored; for there are several places where hot springs issue from the ground—some comparatively near to the east coast, others near to the edge of the central highlands, while there is one district near the extinct volcanic mass called “Ankaratra” where carbonic acid gas issues freely out of the soil. These mineral waters may be classed under the following heads, adopting Dr. Tanner’s classification:—

CLASS 1. *Ferruginous waters*.—I do not know of any springs belonging to this class of which the water has been analysed by Europeans, or which are drunk by the natives, but I have noticed in the iron districts many springs which deposited what appeared to be a ferruginous sediment.

CLASS 2. *Sulphurous waters*.—I believe some springs of this class exist in the iron district of Vonizongo (near the London Missionary Society’s station), about one day’s journey from Antananarivo.<sup>1</sup> The natives declare that there are two or three springs (thermal?) here, the waters of which have a strong odour of sulphuretted hydrogen. A few years ago there was a great rage for these Vonizongo springs, the natives making a “rush” thither in large numbers in order both to drink their waters and to bathe in them.

CLASS 3. *Acidulous waters*.—In the district of “Antsirabé” (near the Norwegian Mission station) are a number of springs of this class, between 400 and 500, it is said. The earliest notice of these springs is in Ellis’s “History of Madagascar,” where the writer calls attention to the simple carbonic acid gas springs, some being dry holes in the soil, marked by the carcasses of grasshoppers and other small creatures which, accidentally falling in, have been suffocated; others being springs of sparkling water, apparently “boiling,” as the Malagasy say, yet sensibly cold to the hand, and by no means unpalatable when drunk. Since the settlement of missionaries in this district a closer examination has resulted in the discovery of thermal springs also. A mound of calcareous tufa, several feet in height, has been gradually formed by the chalky sediment around one of these springs; but this mound can no longer increase in height, because the resident missionary has tapped it in order to lead the water to a bathing-shed near to his house. One or two other bath-houses have been built near this by the Queen’s order. A qualitative analysis I made of water from four springs in different parts of this district showed the presence of calcium, magnesium, sodium, potassium, chlorine, iodine, sulphates, carbonates, and free carbonic acid gas; in temperature, according to a Norwegian missionary, they range from 105° to 110° F.; and as regards the quantity of solids left on evaporating twenty ounces of water from each spring, they gave a result of twenty-eight, thirty-eight, forty, and forty-two grains respectively. An analysis of a spring at the spot would somewhat alter these results, perhaps, as much carbonic acid gas must have been lost by escaping through the cork, as well as by unskilful bottling. The waters of these springs are now being freely used (with good results) by the European doctors in Imerina for cases of gout, rheumatism, syphilitic affections (extremely common in Madagascar), uric acid diathesis, and some other affections;

cases of syphilitic paralysis most especially are benefited by the use of these waters.

CLASS 4. *Iodo-bromated*.—The Antsirabé springs just mentioned are the only waters of this class as yet known to exist in Madagascar. The constitution of them all is very similar, and they are particularly valuable for the iodine which they contain in an easily appreciable quantity; but they do not contain bromine, so far as the means of analysis at my disposal could show.

CLASS 5. *Muriated lithia waters*.—I do not know of any springs of this class in Madagascar. Besides the above-mentioned springs, which are sufficiently known to be classifiable, I have heard of other thermal springs. On my return to England I brought with me two bottles of water (temperature unknown) for analysis, one being taken from a hot spring in the forest, near the town of Ambohimanga (the capital of the forest tribe called “Tanala”), this bottle unfortunately burst on its way to England; the other from a hot spring on the western border of the province of Imerina. Mr. Hailes, of the Pharmaceutical Society, has kindly analysed the water contained in the second bottle, and his statement is as follows:—“The result of my qualitative analysis tends to prove that the sample is a perfectly normal one, that it contains nothing more than an ordinary spring water would. There is a trace of organic matter, which, however, may be due to the bottle being badly corked. The mineral constituents, which amount to only 27·80 grains per gallon, consist of silica, magnesia, iron, alumina, and chlorine, in small quantities, and lime and sulphuric acid to a somewhat larger extent. The water is absolutely free from carbonates, nitrates, sulphides, sulphites, phosphates, and borates. Owing to the small quantity, I have been unable to push the inquiry as far as I should like.”

In connexion with these hot springs in the west of Imerina, I have heard (from a good authority) that many years ago a number of Malagasy, including high officials of the Hava Government, made a pilgrimage to these springs, but, as they never thought of building bath-houses and tanks, their only resource was to sit on low seats with their feet in the hot mud for hours at a time. One of these pilgrims was a young officer, now healthy and strong, then a lad afflicted with paraplegia (syphilitic?), who was put through a course of hot baths by the following simple process: After being stripped, two men took him by the wrists and ankles and dipped him, bathing-woman fashion, into the hot mud.

If the spring water analysed by Mr. Hailes cannot be accredited with these cures, some more alkaline, perhaps iodo-bromated, springs may be discovered at some future time in their neighbourhood.

## NOTES ON SOME OF THE HOSPITALS IN THE CITY OF NEW YORK.

(From a Correspondent.)

DURING the last few years several entirely new hospitals have been erected here, in most of which the leading principles obtaining in hospital construction during later years have been carefully observed, while in the larger and more recent structures there are evidences of rivalry, on points partly experimental, which is as useful as it is commendable.

*The Segregation Plan*.—This principle in a general way prevails in each, so far as the wings are concerned, but in a manner particularly complete has it been carried out in some of them in the case of one or more surgical wards. Even Bellevue, the oldest of the hospitals, never to be outdone in enterprise, has erected in the garden a one-storey ward for surgical patients, and called the Sturges’ Pavilion, and a very pretty ward it is. One feature in it it would be well to notice is the entire absence not only of curtains of any kind but of beds and mattresses. For both of these the substitute is a single sheet of wire matting. This is so well stretched by the four iron bed-posts as not to unduly dip, while the texture of the matting is such that when covered with a double blanket its firmness is not less than its softness. In this ward are two admirable English open fireplaces; their respective chimneys are built, however, so as exactly to obstruct the traffic and view in the middle of the central and only aisle. At one end of this building are

<sup>1</sup> All travelling in Madagascar being on foot, a “day’s journey” averages from twenty-five to thirty miles, rarely more.

single wards intended for the segregation especially of puerperal patients. This pavilion is beyond the main hospital out in the garden, having a separate kitchen, ridge ventilation, and every special appliance to secure sanific conditions. Strange to say, however, I found at the time of my visit not one patient in it, and this for a reason much stranger still,—septicæmia had occurred in it to such an extent that it had been necessary for some time past to discontinue the use of the ward altogether. A pavilion ward, which in every particular is as a surgical ward unequalled in New York, and unsurpassed anywhere, is to be found at the Roosevelt Hospital. This also is of one storey, and in height, width, light, and decoration is perfection. Though completely removed from the main building so far as necessities of excommunication can require, the central kitchens, laundry, heating shafts, and ventilating shafts of the entire establishment are in direct communication with it; all the benefits with none of the evils of a large and well-appointed hospital are thus secured in this ward in an exceptional degree. In the ventilation of this ward one point upon which I have always insisted is carried out. While in summer it can be made direct and intermediate by window and by double ridge, in winter all the fresh air is warm air, yet pure, the exit being by aspiration through a superheated shaft. This principle applied to each basin in the waterclosets secures an absence of odour it would be difficult to surpass. At the Woman's Hospital alone, however, have wards been erected as in Boston, with the express purpose of being burnt down or otherwise completely destroyed within a limited period. In the garden of this hospital there have been erected, some distance apart, several two-roomed wooden cottages. One room is the kitchen, the other an operating and bed-room. In these cottages exclusively the ovariectomies of this hospital are performed. Each cottage is occupied by one patient only at a time, and she stays undisturbed in the room where she was operated upon until it is unquestionably safe and expedient for her to be transferred to a general ward. On the slightest suspicion of contamination of one of these cottages it can be burnt without any loss to be mentioned, or it can be wheeled away intact, and be sold at half its cost for other uses. These truly cottage hospitals, and they alone, amongst public institutions, secure a segregation which is absolute. They imply, of course, special nurses and other extra expenses, which, if the principle be groundless, are unwarrantable. If, however, but in a fractional part the principle be correct, he would be a most unchristian economist who should denounce the extra cost per life as extravagance or waste.

*A Hospital Solarium.*—As yet to the New York Hospital alone, of all the other hospitals in this city, and I believe in this country, belongs the credit of this bright redeeming feature in the always sad and depressing life of the hospital patient. This hospital has not only set the first example of having all its cooking and laundry work done at the top of the house; but beyond all sight, sound, or smell of anything disagreeable it has utilised a part of its roof as a solarium. This solarium, which is directly accessible by the lifts, is a large greenhouse, which combines the farther attractions of an aquarium, herbarium, aviary, museum, art gallery, library, reading room, and drawing room. In accordance with the prime objects in its construction, it secures, all day long, all the sunshine the sun pleases to give, minus the external cold; in summer all the breeze which only such an elevation can receive, while at all times the bay, the harbour, the Hudson river, and the mountains beyond present at one view a scene most bright, varied, and exhilarating. The Bigelow post-mortem table is another point in this hospital not unworthy of notice. This table, like most others of its class, dips towards a centre grating, but by elaborate arrangements beneath this grating and within its central and single leg, are found not only provision for drainage, but for ventilation. On the principle of aspiration, a continual air current downwards through the table leg is said to be obtained of sufficient volume and force to carry away without all offensive emanation during autopsies. I have had no opportunity of personally observing its efficacy, but with this and with the original table of my friend, Dr. Bigelow, in Boston, considerable satisfaction is expressed. For convenience for the operator and thoroughness of drainage, a rim at its edge, and convergent groovings of its surface, after the manner of the corresponding table in the Allgemeine Krankenhaus in Vienna, would seem to me not undesirable. This New York hospital is exactly the antithesis in architectural design

of the new handsome wide-spreading hospital at Chicago. Here in this bijou establishment can be seen in fewer minutes than in any other I know a larger number of the best points in modern hospital construction.

The Manhattan Eye and Ear Hospital is a crowning monument to its originator, Dr. C. R. Agnew, and to his present colleagues. It is situated in a neighbourhood as fashionable as is that of St. George's in London, and in the descriptive account is announced the very sensible, but very un-American, fact that in addition to all the usual appliances for heating and ventilation nearly every ward and room has a fireplace in it, in which particular this hospital is different from and beyond any other I know of in this city.

## Correspondence.

"Audi alteram partem."

### THE "EIRA" ARCTIC EXPEDITION.

To the Editor of THE LANCET.

SIR,—It has been suggested by Dr. Buzzard and others that it would be interesting to know what kind of vegetables were saved from the *Eira*, and in what manner they were preserved and cooked.

1st. *Potatoes*.—Of these we had 150 tins, each containing 6 lb. of whole potatoes, which had been peeled, then half boiled and put into tins; these potatoes were out up in small pieces and boiled with the meat for three or four hours. Messrs. Ritchie and Co., of Peterhead, had preserved them by Mr. Leigh-Smith's special instructions.

2nd. *Carrots*.—Also preserved in 6 lb. tins, and partly boiled. We used them in the same manner as the potatoes, and saved about 180 tins.

3rd. *Edward's Dried Potatoes*.—Of these we had about 150 lb. We used them twice a week, putting, as a rule, 2 lb. into the dinner pot. These thickened the soup wonderfully.

4th. *Dutch Vegetables*.—Of these I cannot speak too highly. We, unfortunately, only saved thirty tins, containing about 10 lb. in each; some were potatoes and carrots, others potatoes and beans, others potatoes and peas. The Dutch preserve every kind of vegetable in these long tins, always mixing a good quantity of fat with them.

5th.—We had several small 1 lb. tins of peas, beans, turnips, macedoine of vegetables, &c., which were used occasionally when a little extra was wanted to celebrate any special occasion.—I am, Sir, yours truly,

W. H. NEALE, M.B., B.S.

Boundary-road, South Hampstead, N.W.

### SCURVY.

To the Editor of THE LANCET.

SIR,—I was struck by two independent observations which occurred in your columns last week with regard to the etiology of scurvy, both tending to controvert the [generally received opinion that the exclusive cause of that disease is the prolonged and complete withdrawal of succulent vegetables from the dietary of those affected.

Thus Mr. Neale, of the *Eira* Arctic Expedition, says: "I do not think that spirit or limejuice is of much use as an antiscorbutic; for if you live on the flesh of the country, even, I believe, without vegetables, you will run very little risk of scurvy." Dr. Lucas writes: "In the case of the semi-savage hill tribes of Afghanistan and Beluchistan their food contains a large amount of meat, and is altogether devoid of vegetables. The singular immunity from scurvy of these races has struck me as a remarkable physiological circumstance, which should make us pause before accepting the vegetable doctrine in relation to scurvy." These observations do not stand alone. Arctic voyagers have long pointed out the antiscorbutic properties of fresh meat, and Baron Larrey, with regard to hot climates, arrived at the same conclusion in the Egyptian expedition under Bonaparte, at the end of last century.

The question now arises, How is it that tropical and arctic experience is at variance with that acquired in Europe? The only explanation that occurs to me is the different circumstances under which the meat is eaten. As is well known, the reaction of freshly killed meat is alkaline,

from the presence of neutral sodium phosphate; after rigor mortis has passed off it gradually becomes acid, owing to the formation of lactic acid, which converts the neutral into acid sodium phosphate, thus:—

Now, in hot climates meat has to be eaten so freshly killed that no time is allowed for the development of the lactic acid; in arctic regions the freezing arrests its formation. The muscle plasma therefore remains alkaline. In Europe meat is invariably hung, lactic acid is developed freely, and the muscle plasma is consequently acid. If therefore scurvy is, as I have endeavoured to show ("Inquiry into General Pathology of Scurvy"), due to diminished alkalinity of the blood, it can be easily understood that meat may be antiscorbutic when fresh killed or frozen immediately after killing, but which may become scorbutic when these alkaline salts have been converted into acid ones by lactic acid decomposition.

In conclusion, Mr. Neale is to be congratulated on his valuable and practical suggestion as to the use of the blood of the animals killed for food as a prophylactic in scurvy. The blood being so rich in alkaline salts no better natural antiscorbutic can be employed, if the view be accepted that scurvy depends upon a diminished alkalinity of that fluid.

I am, Sir, yours truly,

CHARLES HENRY RALFE.

Queen Anne-street, Aug. 28th, 1882.

## THE "RESPIRATOR" IN SYPHILIS.

To the Editor of THE LANCET.

SIR,—The treatment of syphilitic ulcers of the tongue, mouth, and fauces by respiration of iodine and carbolic acid, &c., has proved so successful in numerous instances which have come under my notice of late, that I am desirous of giving it publicity in your columns. For the past two years this form of syphilis has been peculiarly prevalent in this Command, and as usual proved so tedious of cure, and so liable to recur under the ordinary treatment, constitutional and local, generally adopted, that I decided this year to test the efficacy of the "respirator," and I was gratified to find that the results, in all instances, were most satisfactory. The period of trial is as yet too brief to furnish reliable evidence of the constitutional and permanent effects of this treatment; but certain it is that locally its action is most prompt and palpable, all ulcers assuming a healthy appearance generally in forty-eight hours, and wholly disappearing in ten or twelve days. Immediate relief is also afforded from any panic or discomfort previously caused by the disease. After free purgation the only treatment needed is the use of the "respirator" for four hours daily, two morning and evening, after breakfast and tea. The solution I generally use is Coghill's combination of iodine, carbolic acid, and creasote, and I prefer oakum as the material for its retention. The form of "respirator" I have adopted is one I have devised myself, and is furnished with a detachable perforated diaphragm, which admits of its being thoroughly cleansed and purified for use in different cases.

I am, Sir, yours, &c.,

W. S. OLIVER, M.D., Surgeon-Major.

Halifax, N.S., August 10th, 1882.

P.S.—In 1875 I suggested that this method of the administration of medicinal antiseptic agents should be applied to the treatment of cholera, instead of endeavouring to affect the system through the deranged gastro-intestinal channel, and I still feel strongly impressed that if tried it will be found one of the most efficient means at our disposal of administering medicine in this disease.

## CUPAR FIFE.

To the Editor of THE LANCET.

SIR,—My attention has been called to a paragraph in your Scottish Notes of last week in which it is stated that Cupar is afflicted with an epidemic of typhoid fever. That is not the case; but we have an epidemic of scarlatina. Perhaps you will kindly correct this, and oblige, yours truly,

WILLIAM WHITELAW, M.D.,

Medical Officer of Health, Cupar Fife.

August 23rd, 1882.

## SCOTTISH NOTES.

(From our Correspondent.)

DR. PIRRIE, the venerable Professor of Surgery at Aberdeen, has resigned his chair on the ground of advanced years and declining health. At the meeting of the University Court held last week permission was given, and, after the members had individually expressed their high sense of the distinguished services of Dr. Pirrie, it was agreed to recommend that an increase of the usual retiring allowance should be granted. Dr. Pirrie has served the University in the capacity of Professor for the long period of fifty-two years; for nine years as Lecturer on Anatomy and Physiology, and since then in the now vacated chair. Notwithstanding this long record of work, it is questionable if the duties of his chair have ever been more efficiently performed than during the past few sessions; the unfortunate illness which is the immediate cause of retirement having developed itself since April last. The fine form, the ever vivacious countenance, the sympathy, and the enthusiasm of the Professor will be missed by succeeding generations of students at Aberdeen, except as an ever-living tradition; while the place of one of the most impressive lecturers who ever addressed an audience of students will be difficult, if not at present impossible, to fill. After a double course of surgery under Dr. Pirrie, the man who did not know his subject well was an incorrigible dunce or careless idler. Even his most conspicuous fault, repetition through the want of manuscript, was helpful. We may well hope that, as he is now relieved of the duties of the chair, he may be long spared to benefit the profession and the public in his extended sphere of consulting practice.

There is as yet no certainty as to the candidates for the vacancy in Aberdeen. Locally, of course, Dr. Alex. Ogston's name is prominent in the matter, and much sympathy is felt for him in the illness which has necessitated his absence from home at the present juncture. I am not at liberty to say more than that another distinguished investigator and practical surgeon, who has also considerable experience as a teacher, may soon appear as a candidate. Many of the chairs in Scotland have within the past few years been filled by the appointment of men eminent enough as scientific plodders who have not distinguished themselves in the lecture-room or as practical teachers, and in this case I sincerely trust that the eminent teacher now retired may have as a successor one who has the necessary aptitude for exposition. The patronage is in the hands of the Crown.

Dr. Whitelaw, in dealing with an epidemic of scarlet fever at present co-existent with that of typhoid at Cupar, adopts a simple method, which may with advantage be copied by other authorities. The Sanitary Committee did not deem it necessary that the schools should be closed, but that parents should be advised not to send children to school if any member of the family were affected. It is well known that this recommendation is often a dead letter, and Dr. Whitelaw has now had lists of the affected houses forwarded to the authorities of each school, while parents are warned that should they persist in endangering others by sending to school those children who have been exposed to the infection, they are liable to punishment under the Public Health Act. It is also considered of importance that parents on the list should not send their children to school until they have obtained a medical certificate that there is no risk involved. Ten out of forty-two cases of scarlet fever have proved fatal: a decidedly heavy mortality. The epidemic is abating.

At the advanced age of eighty-five years Aberdeen has lost her oldest practitioner, and one known to several generations of medical students. Though holding many appointments, it is as dispensing physician that Dr. John Paterson will be best known. For a period of years, differently defined even by himself, but reaching far back, he held office at the General Dispensary, and students delighted to spend an hour with him more on account of his genial and facetious style, both to pupils and patients, than from respect for his diagnostic powers. Belonging absolutely and unchangeably to the old school, his diagnosis of the fevers, of pneumonia, or of incipient phthisis, was somewhat mixed, but in his superintendence of midwifery cases he was a safe and instructive guide. During his earlier years he did good work in epidemics of cholera and other diseases affecting the

poor, and till the last he was emphatically the poor man's friend. Aberdeen graduates, wherever found, will have pleasant recollections of Dr. Paterson.

At a meeting of the Council of the Dundee University College held last week, Mr. W. Petersen, M.A. Ed., B.A. Oxon., and late scholar of Corpus Christi, was appointed Principal of the College. The various professors will shortly be selected, and work may be expected to commence forthwith. The Council hope to make such arrangement, either with St. Andrews or other university, as will allow of students proceeding to their degrees in the various faculties; but at first the teaching will be confined to science subjects and those necessary in the Arts course. Many are sanguine enough to believe that through this college, favourably situated as it is for practical work, the medical teaching in St. Andrews may ultimately be placed on a footing of equality with the other Scotch Universities, and it is just possible that the science and medical work might be done entirely in Dundee. The newly appointed professor at St. Andrews has a good field for his energies here, and I have reason to think he is not averse to such advantages as combination affords.

Two of the ruffians who recently decoyed and attacked Dr. Whitelaw of Kirkintilloch were brought before Lord Mure at the Stirling Circuit Court, and on Monday were sentenced to penal servitude—the man for eight, and the woman for five years.

### IRELAND.

(From our own Correspondent.)

THE Chair of Natural History in the Queen's College, Cork, is now vacant in consequence of the death of Professor Leith Adams. The appointment is in the hands of His Excellency the Lord-Lieutenant, and the candidate selected will enter upon his duties about the middle of October.

A Belfast paper states that the Government are contemplating the abolition of the Queen's Colleges in Ireland, and that inquiries are being made as to whether the several professors will be willing to compound for a fixed sum, should the institutions to which they belong be closed. I believe the statement to be entirely unfounded, and probably only due to the wish of that section of the Irish people who have always regarded the Queen's Colleges in Ireland with ill-concealed hostility.

The first Matriculation Examination of the Royal University of Ireland was held last December, when 728 candidates sent in their names, but only 614 came forward for examination, and of these 506 were successful. A second matriculation examination takes place this month, and about 600 candidates are expected to present themselves. There has been a fee of £1 charged for the first university examination in medicine of the new University, but as no charge was made for a similar examination in the Queen's University, a legal opinion was obtained, and I believe I am correct in stating that those students of the Queen's University who paid this fee will have the amount refunded. There has been as yet no allocation of the Medical Fellowships, if we except those for chemistry.

Dr. John MacMunn, late resident medical superintendent of Sligo District Lunatic Asylum, who died last April, has left a sum of £200 to the Royal Medical Benevolent Fund Society of Ireland, and £1000 divided among several Irish medical charities.

The outbreak of small-pox in Clonmel is abating, as only one case of the disease was admitted to hospital during last week.

In the case of Hynes, hanged at Cork last week for murder, Dr. Moriarty, the medical officer of the prison, who witnessed the execution, stated that the heart did not cease to beat for thirteen minutes after the drop fell, and that the pulse in the right hand did not cease for five minutes. The neck was dislocated between the fourth and fifth cervical vertebrae, and the spinal cord ruptured.

Dr. MacCabe, Local Government Board Inspector, in his recent half-yearly report on the condition of the South Dublin Union, remarks, that although the workhouse has recently been somewhat relieved of overcrowding in the female infirm department by the transfer of nearly 200 women of this class to Kilmainham sheds, yet he looks forward with great apprehension

to the pressure which appears likely to be made upon the accommodation of the workhouse during the approaching winter. Even at midsummer the workhouse is very full, the male able-bodied department unduly so, and the female able-bodied wards overcrowded. The hospital departments he considers satisfactory, and a desirable improvement has been effected in the reduction in the use of stimulants. Considering the liberal dietary in vogue at this workhouse, the sum total for stimulants appears most startling.

### NEW YORK.

(From our Correspondent.)

#### THE HOSPITAL SUNDAY MOVEMENT.

THE last number of THE LANCET to arrive here contains your editorial remarks on the result of your Hospital Sunday collection. It may therefore be an appropriate moment for me to offer your readers a *résumé* of what has been done in regard to this movement in the United States. I presume the movement must have had long precedence in England, for the first attempt at such an organisation was made in New York in the autumn of 1874, when the Board of Managers of St. Luke's Hospital issued an appeal to the various episcopal churches of New York City for a collection on behalf of their own work, to be made on the last Sunday of the year. This appeal was so favourably received, that from that time to the present the collection has been regularly made.

The friendly interest manifested by the press in this collection, and the reported success of the General Hospital Sunday movement in Liverpool and London, caused the managers of St. Luke's Hospital to believe that the cause of general charity to the sick would be promoted by an appeal to all classes of citizens, in behalf of all the charitable hospitals in the city; and on the 25th of November, 1878, a paper was read by the Rev. George Stuart Baker, the Superintendent of St. Luke's Hospital, before the Board of Managers, in which a scheme for such a general collection was elaborated, and afterwards put in practice. The result, so far, has been as follows—viz. :—

Total collection for 1879.....	\$26,455 07
" " 1880.....	44,371 97
" " 1881.....	42,535 45

This amount has to be credited to New York City alone, as Brooklyn and the adjoining cities did not participate in the movement.

An examination of the amounts contributed by the various denominations shows in striking contrast the manner in which each creed sympathised in the movement. The Roman Catholic Church, the richest religious organisation in New York, contributed nothing. The Episcopal Church headed the list last year with \$17,768; the Presbyterians next with \$2521; then the Hebrews with \$1368; and the Dutch Reformed with \$1071. The powerful organisation of the Baptists gave only \$299, and the Methodists must have ignored the movement, giving only \$157.

The total amount last year was divided between twenty-one city hospitals. The New York Hospital, the Roosevelt Hospital, and the Nursery and Child's Hospital waived their claim to a share; the first two being wealthy corporations, and the latter not requiring aid to accomplish their work.

Last year a four-page pamphlet was prepared, presenting in a tabulated statement the work done at all the hospitals, giving their total receipts and expenses, and the number of patients treated free of charge; also a variety of interesting and important statistics, most useful for distribution before the collection, showing the actual financial condition of the hospitals and their need of public support. If I extract one item, it will show the value of such a report: "The actual number of days of hospital care of adult patients entirely free in the seventeen hospitals during the year was 243,680. These, at the average cost of \$1 15 per day, show \$285,982 expended in the free care of the sick. Of this sum, only \$88,735 was received by these hospitals as income from their invested funds, and they were dependent for the balance on benevolent contributions and appropriations made by the Government of the city."

Last year a Hospital Saturday was organised, being the

last Saturday in the year, the day previous to Hospital Sunday. Your London rules for Hospital Saturday could not be applied here, so an attempt has been made to reach the general public by means of trades and various business pursuits, such auxiliary associations having a common form of constitution and by-laws. This system is too new to be properly developed, but worked well from the start. These auxiliary trade associations have the right to claim a certain amount of medical relief in proportion to their contribution.

The press of New York City has contributed valuable aid to this movement by editorial and other notices, which have placed the object of the Association prominently before the public. The distribution of 50,000 of the printed statement's I have referred to is believed to have done much to increase the fund, presenting such an array of facts, in a form to be grasped without effort by the reader, that no one who reads it could fail to appreciate the force of the appeal.

I had a long talk to-day with the Rev. George S. Baker at St. Luke's Hospital, and feel pleasure in presenting here his suggestion that the Secretary of the Hospital Sunday Movement in London should put himself in communication with those who have enlisted their energies in the same direction on this side. Doubtless the same methods are not applicable for both countries, but a comparison of the working of the systems, and the various rules and regulations which each has adopted, cannot fail to lead to good results, and something may be learned each year by the other's experiences. Mr. Baker will reciprocate any courtesies which the London Secretary of the movement will extend; and will send copies of all printed matter issued by the Association. Mr. Baker says that he has received some of the printed documents of the London Society, but only at second hand, by the thoughtfulness of a friend, and not from the Society itself. Anything sent to me, addressed THE LANCET Post-office Box, 3230, New York, will be sent to the proper quarters; or the Rev. George S. Baker can be addressed at St. Luke's Hospital, West 54th Street, New York City.

I send by this mail to the office of THE LANCET, London, the following printed pamphlets, for the use of the secretary of the London movement, if deemed acceptable:—

1. Statement and Appeal of the Hospital Saturday and Sunday Association for the Year 1881.
2. History of the Hospital Saturday and Sunday Movement in New York City.
3. Report of the New York Hospital Saturday and Sunday Collection for 1880.
4. Report of the New York Hospital Saturday and Sunday Collection for 1881.
5. Constitution and By-laws of the Hospital Saturday and Sunday Association of New York City.
6. Constitution and By-laws of the Hospital Saturday and Sunday Auxiliary Associations, &c. &c.

It may be noticed that the movement has been thus far chiefly confined to New York City, the only exception I know of being the State of Maine, which has observed a Hospital Sunday since 1876. But the New York Executive Committee has addressed to the Mayors of twenty-three large cities a letter in the name of the Association, giving them a history of the movement, the result of the collections so far, and asking them to inaugurate similar movements in their respective localities. The replies received were very satisfactory, and steps have been already taken in some of these cities to follow the lead New York has set; and it is hoped that the Hospital Sunday movement may become a national institution.

In conclusion, I may state that the city government of New York City annually makes an appropriation of its funds for charitable institutions. Might not the rich corporations of London do something of this kind, sending on the 1st of January of each year a cheque for a stated amount to each of the London Hospitals requiring financial help?

August 14th, 1882.

A FINE incident is told of the first bearer company of the Army Hospital Corps in the late engagement at Kassassin. They were, during the recent engagement, by some movement of the troops, isolated. The medical officer in charge refused to allow the interruption in his duty of dressing the wounds which a change of position would have caused, and his forty men filled their haversacks with sand, so as to make a rough shelter, took the rifles of the wounded, and defended their charge until the arrival of the cavalry put an end to the enemy's attack.

## Medical News.

**APOTHECARIES' HALL.**—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on Aug. 24th:—

Maye, John, Kingsbridge, Devon.  
 White, Thomas Harry, Silver-street, Lincoln.  
 Wilson, Mervyn Sappings, Birchington-road, Kilburn.  
 Worthington, Sidney, Enfield, Middlesex.  
 Young, Charles Stewart, Royal Infirmary, Glasgow.

The following gentleman also on the same day passed the Primary Professional Examination:—

London, John E., King's College.

At the recent examination for the Prizes in Materia Medica and Pharmaceutical Chemistry given annually to medical students by the Society of Apothecaries, the successful candidates were—

1st.—John Barker Smith, St. Thomas's Hospital. Gold Medal.  
 2nd.—Thomas Henry Williams, Middlesex Hospital. Silver Medal and Books.

**UNIVERSITY OF GLASGOW.**—In the list published on Aug. 12th of gentlemen who passed the examination for the M.D. and C.M. degrees, the name "John Gopp" should have been printed John Goff.

**VACCINATION GRANT.**—Michael Whitmarsh, M.D., M.R.C.P., of Hounslow, has received the Government grant for efficient vaccination (fourth time).

AN apthous disease, designated by the report "red thrush," is raging in an epidemic form at Malmö, Sweden. The mortality appears to be about 7-30 per cent.

THE Canterbury Board of Guardians are taking steps for the erection of a larger and more commodious infirmary than the one at present in use.

A HOUSE-TO-HOUSE collection was made on Saturday, August 19th, at Hastings, on behalf of the West Kent General and County Ophthalmic Hospital. The sum realised was about four guineas.

**CRIMINAL LUNATICS.**—In the year ending the 29th of September the number charged and detained as criminal lunatics in England and Wales was 827—656 males and 216 females.

A CORRESPONDENT of the "City Press" directs attention to the filthy state of Fleur-de-Lis Court, Fetter-lane. Complaints on the matter have, it appears, unavailingly been made to the City authorities.

AT the annual meeting of the governors of the Stratford-on-Avon Infirmary, held recently, the honorary physician, Dr. Kingsley, announced a donation of £6000 and a site for the proposed new building, the bequest of a gentleman whose name was not given.

THE committee of the North-west London Hospital for Sick Children are in treaty for the purchase of two nearly completed semi-detached houses in Ball-street, Edgware-road, for the purpose of converting them into a hospital for the treatment of children's diseases.

By the will of the Marquis of Conyngham, lately deceased, it appears he has not forgotten his medical attendant's, having bequeathed to "his friend," Mr. Edgecombe Venning, F.R.C.S., of Sloane-street, £200; and a like sum to his resident medical attendant, Mr. Robert Hippisley Cox, M.R.C.S. The will was sworn under £118,000.

AN inquest was held this week by Mr. Langham, at the board-room, Mount-street, Grosvenor-square, on the body of Mr. G. H. Ross, L.R.C.P.L., who died in the infirmary, to which he was removed in a comatose state. The post-mortem examination revealed the presence of compression of the brain due to fracture of the skull. A verdict of "Accidental death" was returned.

**MARGATE SEA-BATHING INFIRMARY.**—On Monday Sir Erasmus Wilson, at a meeting of the Governors of this Infirmary, handed over the key of the new wing of the building, to be named the Erasmus Wilson Wing, which has been built by him at an estimated cost of over £30,000. The wing includes two large day-rooms, and four dormitories, each to contain 16 beds, with a swimming-bath capable of containing 15,000 gallons of sea-water.

## BOOKS ETC. RECEIVED.

- CHURCHILL, J. & A., London.  
On the Climate and Fevers of India: The Croonian Lectures delivered at the Royal College of Physicians, 1832. By Sir Joseph Fayrer, K.C.S.I. &c. pp. 278.  
St. Thomas's Hospital Reports. New Series. Edited by Dr. Robert Cory and Mr. Francis Mason. pp. 419.

Eigeon.—On Croup, its Nature and Treatment; by John Moir, L.R.C.P.Ed.—Leisure Hour, Sunday at Home, Boy's Own Paper, Girl's Own Paper, Good Words, Sunday Magazine, for September.—De la Constitution Élémentaire des Tissus; par le Prof. A. Estor.

## Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning at the latest.

- ALFORD, CHARLES EDWARD, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Misterton District of the Beaminster Union.
- BEATTIE, JOSEPH ALOYSIUS, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Government Health Officer for Port Jackson, N.S.W., vice Alleyne, resigned.
- CLAYWORTH, CHARLES CREASY, L.R.C.P.Ed., M.R.C.S., has been appointed Resident Medical Officer at the Sydney Hospital, N.S.W.
- COATES, WILLIAM, M.R.C.S., has been appointed Resident Accoucheur to the London Hospital, vice C. E. Jennings, resigned.
- CORBIN, THOS. WILSON, M.R.C.S., L.S.A.Lond., has been appointed Visiting Medical Officer to the Home for Incurables, Adelaide, Australia.
- CRESSWELL, NATHANIEL ENGELHEART, M.D.St.And., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Blisworth District of the Towcester Union.
- HODGSON, G. G., M.R.C.S., has been appointed Medical Officer to H.M. Post Office, Liverpool, Bootle Division.

- HOLLAND, JAMES CALLANAN, L.K.Q.C.P.I., L.F.P.S.Glas., has been appointed Medical Officer to the Dungarven Dispensary District of the Dungarven Union, vice Anthony, deceased.
- LAING, R., L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer of Health for the Cowpen District, Blyth, Northumberland.
- MACQUEEN, ARCHIBALD JOHN, F.R.C.S.Ed., L.R.C.P.Ed., has been appointed Government Medical Officer for the District of Forbes, N.S.W.
- PEARCE, THOS. FRED., M.D.Brux., L.R.C.P.I., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Milland District of the Midhurst Union.
- PENTLAND, ALEXANDER, M.B.Dub., L.R.C.S.I., has been appointed Medical Officer to the Casualty Hospital at Port Lincoln, South Australia.
- SPENCER, WALTER, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Gringley District of the East Retford Union.
- STEWART, DOUGLAS EDWARD, M.B., C.M.Ed., has been appointed Medical Officer to the Pentridge Stockade, Coburg, Victoria.
- VISE, CHRISTOPHER, M.B., M.R.C.S., has been appointed House-Surgeon to the Infirmary, Tunbridge Wells, vice J. B. Footner, F.R.C.S.Eng., resigned.
- WAINWRIGHT, CHARLES HENRY, M.R.C.S., has been appointed Medical Officer for the Howden District of the Auckland Union.
- WRIGHT, ADAM HENRY, M.B.Toronto, M.R.C.S., has been appointed Physician to the Toronto General Hospital.

## Births, Marriages, and Deaths.

## BIRTHS.

- BROKE-SMITH.—On the 27th ult., at Lipson-terrace, Plymouth, the wife of P. Broke-Smith, M.D., Brigade Surgeon, Army Medical Department, of a son.
- DUNLOP.—On the 17th ult., at 50, David-place, St. Heller, Jersey, the wife of Andrew Dunlop, M.D., of a son.
- GROSS.—On the 26th ult., at St. Saviour's Infirmary, Westmoreland-road, Walworth, the wife of Charles Gross, L.R.C.P.Lond., M.R.C.S.Eng., Medical Superintendent, of a daughter.
- LORD.—On the 26th ult., at Wilton House, Landport-terrace, Southsea, the wife of Frederick Lord, L.R.C.P., L.R.C.S.Ed., of a son.
- O'DONNELL.—On the 18th ult., at Darlington-street, Wigan, Lancashire, the wife of William O'Donnell, L.R.C.S.I. &c., of a daughter.

## MARRIAGES.

- BROOK—READ.—On the 31st ult., by licence, at Holy Trinity Church, Stroud, by the Rev. Edward Hugh Hawkins, B.A., Vicar, Miles Brook, Esq., of Shepley, Yorkshire, to Sidne Sara Symington Scriven Read, Matron of Stroud Hospital.
- DRUMMOND—WILSON.—On the 24th ult., at Devonport, James Drummond, M.D., of South Shields, to Charlotte, elder daughter of the late William Wilson, of Wimborne Minster, Dorset.
- FERGUSON—ROSTRON.—On the 23rd ult., at All Saints', Cheddle, Hulme, John Ferguson, Surgeon, of Stockport-road, Manchester, to Emily, second daughter of R. H. Rostron, of The Ramillies, Cheddle, Hulme.
- JACKMAN—RADCLYFFE.—On the 23th ult., at St. Thomas's Church, Camden-square, William Thomas Jackman, M.R.C.S., L.S.A.Lond., of Coggeshall, Essex, and eldest son of Dr. Jackman, of Stoke Newington, to Edith, daughter of the late Edward Radclyffe, Esq., of Camden-street, and of Mrs. Radclyffe, of Rochester-square, Camden-road, N.W.
- PURTON—JONES.—On the 23rd ult., at Christ Church, Linnet-lane, Liverpool, Astley Rufford, elder son of the late Astley Purton, M.D., of Alcester, Warwickshire, to Catherine Elizabeth, daughter of the late Anthony Jones, of Liverpool.
- TWEEDY—MEREDITH.—On the 26th ult., at St. Peter's Church, Dublin, Henry Colpoys Tweedy, M.D., son of H. Tweedy, M.D., to Alice Maud, daughter of the late Capt. T. J. Meredith, of Cloonmahon, Collooney.

## DEATHS.

- BANNISTER.—On the 22nd ult., at Great Malvern, Alfred James Bannister, M.D., of Addison-terrace, Notting-hill, aged 48.
- CORNEY.—On the 25th June, at Suva, Fiji, Orlando Pridham, the only and beloved child of Bolton Glanvill Corney, M.R.C.Eng., Government Medical Officer, Fiji, and of Evelyn, his wife. He died, to the grief of all who knew him, after three weeks' suffering, from sunstroke, aged 4 years and a half (nearly).
- DOLTON.—On the 19th ult., at Lee-road, Blackheath, William Blucher Dolton, M.D., aged 63.
- GARDNER.—On the 22nd ult., at Bungay, after three days' illness, James Gardner, M.R.C.S., L.S.A.Lond., M.R.C.P.Ed., aged 65.
- MOREHEAD.—On the 24th ult., very suddenly, at Wilton Castle, Redcar, Yorkshire, Charles Morehead, M.D., F.R.C.P., C.I.E., late Bombay Medical Service, aged 75.
- ROBERTSON.—On the 25th ult., at Albany-street, Edinburgh, William Robertson, M.D., F.R.S.E., in his 65th year.
- TICEHURST.—On the 25th ult., at the house of his father-in-law, J. Head, High-street, Lewes, Surgeon-Major Ticehurst, late of the Bombay Army, aged 50.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments, and Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*We cannot prescribe, or recommend practitioners.*

*Local papers containing reports or news-paragraphs should be marked.*

*All communications relating to the editorial business of the journal must be addressed "To the Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

### THE STUDENTS' NUMBER OF THE LANCET

will be published on Saturday next, Sept. 9th. Those gentlemen holding official situations connected with Medical Institutions in the United Kingdom, who have not yet forwarded the necessary information to our Office for publication in that number, are earnestly requested to send it *without the delay of a single post*. It will be esteemed as a favour if the needed alterations be made on the slip forwarded from this Office, so that risk of error may be avoided in the course of perusing bulky prospectuses.

#### THE LAST THING IN INCUBATION.

M. TARNIER, the surgeon of the Maternity Hospital in Paris, struck by the great mortality among infants prematurely born and those which are very sickly after birth, has conceived the ingenious idea of constructing a box which is almost exactly similar to the incubators used for poultry. This box is divided into two compartments—the lower one being used as a reservoir for hot water, while the infant is placed in the upper one, which is well stuffed at the sides and fitted with a sliding glass cover. The temperature is maintained at 86 degrees Fahrenheit, and M. Tarnier has found that by keeping infants in the incubator for a period varying from two days to six weeks their vitality is enormously improved. He has made experiments upon five six-months children, six seven-months, and thirteen eight-months children, and he has only lost two of them, whereas, according to his statement, three-fourths of them would have died but for this adventurous aid to vitality.

M. N.—Registration is no longer necessary at the Royal College of Surgeons, the duty having been undertaken by the Registrar of the General Medical Council, Oxford-street, from whom all particulars may be obtained.

#### UGHT DISEASED MEAT TO BE USED AS HUMAN FOOD?

*To the Editor of THE LANCET.*

SIR,—I wish, through the medium of your columns, to ask the opinion of medical officers of health on the following case.

A cow, which had been previously ailing, gives birth to a calf, and on the following day it is slaughtered, the meat dressed and brought into market. I am consulted as to the flesh being fit for human consumption, and finding on examination that it is soft and flabby and dark in colour, with an alkaline reaction to litmus paper, and taking into consideration that the cow had been under veterinary treatment for several days, had been killed so soon after parturition, and had had physic administered to it, I condemned the meat. Acting on my advice, the Board of Health instituted an action against the butcher, and the case is heard before the local magistrates, who, after a lengthy trial, find the meat not unfit for human food.

Was I justified in condemning the meat? The magistrates by their verdict say I was not, but, as this may be made a test case, I should like the opinion of any of my medical brethren who may feel interested in the matter and who may feel qualified to speak on the subject. I should perhaps mention that a practitioner from a neighbouring town gave evidence on the opposite side, and gave it strongly as his opinion that such meat should not be condemned. He had not seen the meat. I should like to know, seeing that all authorities on the subject were entirely disregarded, what are the circumstances under which meat ought to be condemned and destroyed as unfit for human food.

I am, Sir, yours truly,

August 20th, 1882.

MEDICAL OFFICER OF HEALTH.

#### CHARGES FOR DEATH CERTIFICATES.

IN spite of "M.," a writer in the *Pall Mall Gazette*, we do not believe it is the rule of medical men practising among the poor to charge for death certificates. At any rate, it is a rule more honoured in the breach than in the observance. In the case which occasioned the coroner's reflections the practitioner was careful to explain that his charge was not for the certificate, but for attendance.

*Association of Fellows.*—An old correspondent thoroughly endorses the excellent suggestion made by Mr. Tweedy in his letter, published in THE LANCET last week, that the meeting should be held the day before, or, if more convenient, early on the day of the annual election of Fellows into the Council of the Royal College of Surgeons, and suggests either the Freemasons' Tavern or the Inns of Court Hotel as being convenient for the purpose.

#### THE INFECTIVE POWER OF DIPHTHERIA.

*To the Editor of THE LANCET.*

SIR,—I shall feel obliged by your answering the two following queries under their respective headings.

A. What is a safe period of quarantine after recovery from diphtheria? or, in other words, how long after apparent recovery from the disease can it be communicated? I have heard of an instance where it was said to have been communicated to another person two months after recovery.

B. Be so good as to state your opinion of the conduct of a medical man who, called in to see a case which he pronounces to be diphtheria, does not recommend the isolation of the patient, who is the youngest member of a family of twelve children, the eldest of whom is sixteen. I enclose my card.

I am, Sir, yours faithfully,

August 23rd, 1882.

X. Y. Z.

\*. A. We are not aware of any sufficient data which warrant a decided opinion on this point. The poison of diphtheria probably clings longer to the infected room and house than to the infected person, and recorded instances tend to show that where a second attack had occurred as long as two months after recovery, the source of infection has been the infected premises rather than any infected individual. Under ordinary circumstances, when thorough disinfection of premises and clothing has been resorted to, the lapse of a fortnight after the disappearance of all local signs of disease may be regarded as a safe interval. Such local lesions as the secondary paralyses need, in all probability, not be taken into account.—B. The infectiousness of diphtheria by personal communication has been so abundantly proved, both by experiment and experience, that we can hardly conceive such circumstances as are referred to, unless the remaining members of the family have had a prior attack. And even then the risk is by no means unimportant, second attacks being far from unusual.—ED. L.

*Metalloid.*—No. The tendency of recent observation, both anatomical and clinical, is to establish a contrary view.

Mr. John McNaught.—We do not think that we have anything more to say on the subject of our correspondent's views.

Dr. Taylor's (Scarborough) communication is unavoidably held over.

#### COW'S MILK DURING THE PERIOD OF RUT.

*To the Editor of THE LANCET.*

SIR,—I can quite corroborate the statement of your correspondent, Dr. Alex. Napier, of Glasgow, respecting the effect of cow's milk during the period of rut, although I am unaware of any alteration in the composition of the milk during that period. On investigating the causes of some infantile diarrhoea lately, I found that in most cases the parents had been very particular in obtaining milk from one cow for their infants. Some of these children had the milk from the same cow, and these were attacked with diarrhoea at the same time, and that time corresponds to the period of rut in the cow. I have little doubt but that this was the cause of the diarrhoea in this instance, and on a previous occasion I noticed the same probable cause. I believe that this would be a much more frequent cause of illness than it is at present but for the fact that cowkeepers as a rule pay little attention to their customers' orders for milk from one cow. Whenever the opportunity has occurred I have advised parents not to give any such order, believing this to be a popular and injudicious error.—I am, Sir, yours, &c.,

August 26th, 1882.

EDWARD WALFORD,  
Medical Officer of Health, Ramsgate.

Mr. James Richards would oblige by obtaining for us further particulars, when the subject shall have attention.

Mr. William Thomson (South Yarra).—The matter has not been overlooked.

#### "BICYCLE (AND TRICYCLE) RIDING."

*To the Editor of THE LANCET.*

SIR,—The concluding sentence in Mr. Creswell's reply to "F.R.C.S." suggests to me to state that I am acquainted with persons afflicted with hernia who always dispense with their trusses when tricycle-riding. I know two bicyclists—racing men—who have had to give up riding on account of varicose veins. Both attribute their condition to bicycle-riding. Can they be mistaken?

I am, Sir, your obedient servant,

W. H. STACPOLE WESTROPP, L.R.C.S.I., &c.  
Lisdoonvara, August 25th, 1882.

## MEDICAL ADVERTISING AT TUNBRIDGE WELLS.

THE *Tunbridge Wells Gazette* advertises weekly the names of its staff and the number of its in- and out-patients. This seems to us superfluous, to say the least. If the committee of the charity thinks the advertisement of the work done helps the funds, well and good. But the weekly advertisement of the medical officers is a contravention of that spirit of quietness in which medical and benevolent work should be done.

*Drachm.*—The report of a case will appear in an early number of THE LANCET.

## THE POSITIVE TREATMENT OF GONORRHEA.

To the Editor of THE LANCET.

SIR,—As a regular reader of your valuable journal I am frequently forced to the conclusion that many of the theories advanced would never find ventilation had the writers themselves had any practical personal experience of the pain their ill-begotten remedies inflict upon the patients they unfortunately try their experimental treatment upon. On no one subject has this feeling intruded itself upon me in reading the various articles, letters, &c., more than on that of the so-called "abortive treatment of gonorrhoea."

Of course it is very wicked to confess that ever I had such an ailment, but truth compels me to say that, after seeing much practice at the Manchester Lock Hospital, and having duly passed my M.R.C.S. examination and being actively engaged in practice, to my very great surprise one day I found myself (for the first time in my life) enjoying the promise of a smart attack of urethral inflammation. Now, whilst the prescribing of medicine for others and pocketing the reward of my industry (especially the latter) has constituted one of the chief enjoyments of my life during the last twenty years, I have to confess to an all but utter inability to swallow any of the nauseous compounds in which I daily dabble. You may fancy my exultant feelings in the prospect of having to face the stern reality of balsam, cubebs and co. Of course I immediately consulted the authorities (I think we always do this when matters so nearly come home), the result being that, all things considered, I came to the conclusion that the treatment recommended in "Druitt's Vade Mecum" was about the most sensible and practical treatment I could find, and one deserving honest trial. Of course, too, I was a bachelor, so had every opportunity of doing every justice to the two grains to the ounce of nitrate of silver injection, but as I sat for hours after its use nursing that weak solution, and the extreme and persistent pain it occasioned, and then shrieked out with agony when forced to micturate, I reluctantly was forced to the conclusion that Dr. Druitt never had this ailment, or, if he had, had certainly written his book before trying the remedy he recommended. Afterwards, when suffering from severe orchitis brought on by this injection, I "unanimously" came to the direct decision that he knew nothing at all about it. For two whole years I held courageously to a gleet discharge, set up entirely by this insane treatment; but eventually, to get rid of it at the cost of a persistently recurring irritability of the neck of the bladder (for which I hold this so-called "abortive treatment" entirely responsible), sulphate and chloride of zinc are all but equally painful, whilst such astringents as tannin, &c., in arresting too suddenly the discharge (which is but the product or result of the acute inflammation) are sure to be productive of as much harm as good. Now, as against this abortive treatment of this ailment I will tell your readers of a most positive cure for gonorrhoea, one at least which, based upon a large experience, I have never known to fail, and which possesses the advantage of being as palatable as most remedies which we are called upon to use in our every day experience of other ailments. Having, as I before asserted, a somewhat considerable practice in this direction, I get one pound of roughly ground cubebs (I grind my own, and so can rely upon its freshness); this I put into a 200 oz. or wide mouth bottle of commerce; to this I add 2 oz. of the iodide of potash, filling up my bottle with cold water, into the mouth of which I drop several large lumps of camphor, simply to make it keep. This I shake up two or three times a day for a few days, of course keeping it in a very cool place, afterwards pouring off the clear infusion, which I administer to my patients in regular consecutive doses.

If asked why I mix it in this wholesale fashion, I answer—for convenience, and that it may have an opportunity of macerating, and then settling. The spent cubebs I throw away. I add cold water in order that it may keep the longer, and prefer to give only the infusion, so as not to run the risk of choking my patients with drachm doses of the powder. If further questioned why I give them iodide of potash or what its curative advantages are, I honestly admit I cannot tell. All I know is that it neutralises any acidity in the urine, and, from my experience, speedily kills the virus of the poison much more effectually than any other preparation of soda or potash does. In my experience all injections are mistakes; at least, if ever I use any at all, I never but employ an infusion of cubebs, to which I add one grain of morphia. This I direct to be used warm, and only to be passed a short distance down the passage of the urethra.

Perhaps there is nothing new in this treatment—very likely not. Cubebs is a remedy as ancient as the hills. The worst is that when given in the bulk it is readily recognised, and at the best is very unpalatable. Its infusion, however, is much more easily taken. It, with the potash, soon cured me, whilst in my hands it has cured all to whom I have administered it.

Trusting it may be found as effectual in the hands of others, with many apologies for the sad confessions I have had to make, permit me, Sir, to subscribe myself yours, &c.,  
M.R.C.S. Eng.

August 29th, 1882.

## CIVIC EXPENSES.

FROM the annual report of the receipts and expenditure of the City of London, which has just been published, it appears that the expense of the *conversazioni* to the members of the International Medical Congress last year amounted to £2099. The sum of £2596 appears as the amount required for the sanitary expenses of the Port of London.

*Mr. Alfred Wright.*—The advertisement is a very unprofessional one, which would be difficult of justification. The author cannot expect professional recognition.

*Mr. Sprint's* attention is directed to a general notice in another column.

## "THE MALE URETHRA."

To the Editor of THE LANCET.

SIR,—Not having observed in the numerous works on physiology any reasons assigned for the various diameters and directions of the male urethra, I venture to offer a few remarks on the subject.

Apart from nature's economy in regarding the penis as an organ of generation, I contend that the various dimensions and directions of the calibre of the male urethra serve a twofold purpose.

1. To offer as little resistance as possible to the flow of urine, and so reduce friction to a minimum.
2. To cause the flow of the fluid to be propelled from the extremity of the urethra with as much force and with as perfect a stream as possible as compared with the propelling power.

In order that these propositions may be fully appreciated, I can give no better proof than by referring observers to instances where patients have either had ill-developed urethras or a part has been removed through malignant disease, &c., for in such cases the patients have not had the slightest control in directing the stream during micturition, the fluid dribbling, as it were, in all directions, notwithstanding that the development and tone of the bladder have been natural, thus rendering the existence of the unfortunate sufferer perfectly miserable when he is called on for nature's relief.

As to the first proposition, if the calibre of the urethra were the same throughout, a considerable part of the force exerted by the muscular contraction of the bladder would be expended in overcoming the frictional resistance of the stream of urine offered by the entire area of the canal; but as the orifice in the membranous is smaller than that in the spongy portion, the urine flows through the latter without, comparatively speaking, any impediment, but in a somewhat irregular manner on account of the various eminences and depressions of the surface and the positions in which the spongy portion may be directed during micturition, so that the stream is again slightly contracted by the smaller calibre of the meatus, and this tends not only to correct the somewhat irregular stream, but also to increase its velocity. Perhaps it may not be out of place, in order to illustrate my meaning with regard to the last remark, to compare it with an ordinary garden hose. It may readily be seen that when water is allowed to flow from the hose without being constricted by the brass nozzle, it does so in a stream corresponding with the diameter of the hose, but has only a very slight velocity. If, however, the orifice of the hose be contracted, it flows with considerable velocity.

With regard to the second proposition, I am of opinion that the calibre being somewhat of an oval shape and changing its long diameter from the horizontal to the vertical direction, the course, precision, and force of the stream are regulated as in the rifling of a gun. This may be seen when the urine passes through a catheter, the stream changing its peculiar twist, so to speak, and corresponding in shape when issuing from the catheter with the bore of the tube.

I am, Sir, yours truly,

R. FITZROY BENHAM, M.R.C.S.

Baron's-court, S.W., August 19th, 1882.

## SCARLATINA AND PUERPERAL FEVER.

To the Editor of THE LANCET.

SIR,—In response to Dr. Sworn's request, I send particulars of a case I attended some time ago, which somewhat corresponds with the one he reports.

I was sent for in great haste to a case of severe flooding, the patient being seven months pregnant with her eighth child. On my arrival I found the patient on the bed in a small room over a provision-shop, and in a crib by the side of her the body of a child recently dead of scarlatina. Not being able to get the child removed, and the patient continuing to lose large quantities of blood, I at once made an examination, and found it a case of complete placenta previa; so without wasting any time, as the patient could not have stood further loss, I introduced my hand into the vagina, and having dilated the os sufficiently, swept the placenta clear from its attachment, seized the feet of the child, and delivered; then pressed off the placenta, gave a dose of extract of ergot and brandy, and left the patient with a firmly contracted uterus, and the child living. I returned shortly after and had the crib covered with disinfectants, as well as placing them about the room. I was not able to get the child removed for a day or two.

This case, considering the excessive hemorrhage and the small, close room and dangerous surroundings, did fairly well, although the temperature rose as high as 103°. Liquid extract of ergot was administered during the first day or two after delivery, and subsequently decoction of cinchona and ammonia. I have since delivered the patient of a fine, healthy child at full term. The above is simply an outline of facts, opinions being omitted.—I am, Sir, yours &c.,

Appleby Magna, August 22nd, 1882.

CHAS. S. RICHARDSON.

## HEREDITARY LINEAMENTS.

It was Dr. Oliver Wendell Holmes to whom, as he was waiting for a prescription, the druggist said: "That is my son, sir, sitting by you; don't you think he looks like me?" "Well, yes," replied the poet, "I think I can see some of your lineaments in his face."

*An Old Member.*—Complaint should at once be made to the secretary of the Royal College of Surgeons, as the Calendar is about to be sent to press, and on satisfactory proof the name and address will be restored.

## MORBUS CORDIS.

To the Editor of THE LANCET.

SIR,—The following lines were composed this morning and written with his left hand by a patient in the Radcliffe Infirmary suffering from complete right hemiplegia, with occasional spasm in the left side of the face and the left arm. He is a ship's engineer, and has a face which reminds me of student days and old Keeley. As we have no lady-doctor in Oxford, the symptoms he describes must have been felt in the great metropolis.—I am, Sir, your obedient servant,  
Oxford, August 20th, 1882.

H. M. TUCKWELL.

## TO A LADY DOCTOR.

(Complaint of patient, an affection of the heart.)

Yes, doctor, your physic I've taken,  
That surely should conquer my ill;  
The bottle was solemnly shaken,  
I dote on those dear little pills.  
I've followed your rules as to diet,  
I don't know the taste of a tart;  
But though I've kept carefully quiet,  
The pain's as my heart.

Of course you've done good: consolation  
Seems dawning. And yet, it is true,  
I fancy the light of your presence  
Does more than your physic can do.  
I'm well when you're near; but, believe me,  
Each day when fate dooms us to part,  
Come strange sensations to grieve me—  
That must be the heart.

Your knowledge's truly stupendous,  
Each dainty prescription I see;  
I read "Haustrum-statis-somnibus,"  
What wonder you took the M.D.?  
I hang on each word that you utter  
With awe Æsculapian art,  
But feel in a terrible flutter,—  
It comes from the heart.

Have you ever felt the emotion  
That stethoscope ne'er could reveal?  
If so, you'll perchance have a notion  
Of all that I've felt, and still feel.  
Oh say, could you ever endure me,  
Dear doctor! You blush and you start!  
There's only one thing that can cure me—  
Take me—and my heart!

*Staff Surgeon.*—The salaries of the Directors-General of the Army and the Navy Medical Departments are put down at £1500 and £1300 per annum respectively. A Deputy Inspector-General in the Navy receives £720. The cost of naval medical establishments at home and abroad amounts to £65,445. The expense of carrying out the Contagious Diseases Act is £14,800 per annum, whereas in the Army it is only £6360.

## PRECAUTIONS AGAINST DROWNING.

To the Editor of THE LANCET.

SIR,—Allow me to add a few remarks to your very useful suggestions on this subject in "Annotations" of the 10th ult. It is most important that everyone who enters the water should be able to float, and a knowledge of the art of swimming ought to be more general than it is. The "belts" which you describe would be admirable for timid bathers, but the most expert swimmers are in danger of drowning if they are ignorant of other precautions, the neglect of which is the cause of most of the bathing accidents that occur during the so-called "drowning season." A knowledge of the simple laws of physiology might avert many a fatality of the kind. The teaching of such simple rules bearing on the laws of life may be brought within the capacity of all school children; indeed, this branch of knowledge should be made a part of the educational course in all board and other schools.

A case occurred recently at a sea-bathing town on the South Coast, and I relate it as an instance of many similar cases, which, however, are not always so well investigated. A youth went into the sea to bathe. He suddenly sank, and the body could not be recovered till life was extinct. It was known that the lad had partaken of a meal just before going to bathe, and a post-mortem examination revealed the fact that the sudden immersion in the water while the stomach was full of food had acted upon a weak heart, and the collapse which had caused the body to sink would no doubt have been attributed as usual to cramp of the lower extremities if the true cause of the casualty had not been elicited by the evidence at the coroner's inquest.—I am, Sir, yours obediently,  
August 21st, 1882.

M. A. B.

## AN EXTRAORDINARY CASE OF EARLY PUBERTY IN A BOY.

To the Editor of THE LANCET.

SIR,—The following case is, I think, worthy of being put on record:—W— is now six years and seven months old, having been born on January 21st, 1876. A week or two ago I saw him whilst bathing, and was greatly surprised to see that his genital organs were as fully developed as in the adult, and his pubes covered with a thick crop of dark brown hair, presenting the appearance of a youth of seventeen or eighteen; hair is also commencing to grow on his upper lip. His height is about 4 ft. 9 in., and he is big and muscular in proportion, but I regret that I am unable to give his weight and chest measurement. His voice for more than a year has been gruff and hoarse as it usually is in puberty, and his grandmother tells me that he has had hair on the pubes since he was three years of age. He is so wild and mischievous that she has had to apply to the magistrates to have him sent to an industrial school, which they consented to do, and he has now been committed for five years. A few days ago he took away a tradesman's cart, upset it on the roadside, cut the harness into pieces, and galloped the horse about till he was tired of the fun, and then let it go. His clothes were taken away from him, and he was put to bed to keep him from further mischief. He, however, managed to find his grandfather's best black trousers, cut off the bottoms so that they might fit him, and escaped through the window. One day recently he found some pigs straying, and drove them some miles to a butcher and tried to sell them; failing to do so, he gave them away to some one he met. He required three policemen to take him to the workhouse (to which he was sent until arrangements could be made for his removal to the industrial school), and when they had carried him there face downwards, as they were compelled to do, he smashed a bedstead into atoms, kicked the plaster off the walls, cursed and swore in a most fearful manner, and had to be removed to the police-station for safety. He was not a large baby at birth, but grew rapidly after twelve months. He commenced to cut his permanent teeth between four and five years of age. His father is in a lunatic asylum, suffering from melancholia. I have known the child since birth, and am perfectly certain of his age.

I am, Sir, yours truly,

Gillingham, August 24th, 1882.

T. WOODS, L.R.C.P. Lond.

*Dr. Macnab.*—The terms of the bond being precise, the answer must be in the negative.

## "THE CAUSE OR CAUSES OF ACUTE TONSILLITIS."

To the Editor of THE LANCET.

SIR,—As the cause of tonsillitis has so recently been under discussion allow me to add my quota, not as to the cause, but rather as an adjunct to the treatment. My reason for making it public is that, although I have told it to numbers of medical friends, not one ever heard of it. It is so simple and at the same time beneficial and useful in all diseases of the throat where there are difficulty and pain in swallowing, that I trust the profession will try it. The method is as follows:—Stand directly in front of the patient, and pull downward the lobes of the ears; then tell the patient to swallow: he will do this without pain. I cannot explain the theory. I will leave that to others more scientific. The fact I only state, and am so fully convinced of its beneficial application that I trust it will be an answer to any trespassing upon your notice.

I am, Sir, yours truly,

Grantham, August 22nd, 1882.

G. GREWCOCK, M.R.C.S., &c.

*Surtorius.*—The charges are quite reasonable. But clergymen need education in the payment of medical bills.

## "A METHOD OF APPLYING LIGATURES TO VEINS."

To the Editor of THE LANCET.

SIR,—In Dr. H. Sydney's paper on the above, which appeared in THE LANCET on Saturday last, he demonstrates how he applies a "reef-knot." I have amused myself by placing a penholder under a cloth to represent a vein under the skin, and tried to produce the reef-knot as Dr. Sydney describes. Out of numerous efforts I succeeded in tying a reef-knot, but not to be repeated. Each was a granny or worse. It may be my awkwardness, but I would much like to hear from many of your readers whether the reef-knot can be "correctly and securely tied subcutaneously" under ocular demonstration. It would never do to attempt the operation if it was only a haphazard whether one tied the ligature with a reef-knot or a granny.

I remain, Sir, your obedient servant,

August 27th, 1882.

F. A. P.

A Father will do well to consult a medical man on the question he puts to us. We do not give advice.

## "SULPHIDE OF CALCIUM IN CANCER."

To the Editor of THE LANCET.

SIR,—In your last issue Dr. Barton relates three cases of cancer which, "after operation," he treated with sulphide of calcium. I notice that he has omitted the dates of the operations, and also the dates when he last saw the patients. He will see at once that this alone will not enable the profession to form any judgment in the matter, adverse or otherwise, as it is no uncommon thing for a cancer patient after operation to go on well for some time without any treatment at all. Ringer has shown the efficacy of sulphides in many ailments and diseases, but I have never met with the sulphides in cancer treatment.

I am, Sir, yours, &c.,

Belper, August 28th, 1882.

EDWARD GAYLOR.

## COTTAGE HOSPITALS.

DR. LUCIUS W. BAKER, of Baldwinville, Massachusetts, in a paper read at a recent meeting of the local medical society, strongly advocates the establishment of cottage hospitals in different parts of that State. The *New York Medical Record* supports the suggestion, and remarks that in every State in the Union there is a great scarcity of hospital accommodation outside of the large cities.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Woods, Gillingham; Mr. Jas. Hall, Isle of Man; Dr. Whitelaw, Cupar, Fife; Dr. Leslie Jones, Blackpool; Mr. Lloyd, St. Albans; Dr. Tuckwell, Oxford; Dr. Adams, Dumfries; Dr. Kirchner, Würzburg; Mr. Ashton Warner, London; Dr. Andrew Marshall, Preston; Mr. Moir, London; Mr. Corsellis, London; Mr. Walford, Ramsgate; Dr. Finlay, Navaia; Dr. Norris, Birmingham; Mr. Meadows, Hastings; Mr. Hedgcock, London; Mr. Jennings, London; Dr. Fergusson, Peebles; Mr. Gaylor, Belper; Mr. McDougall, Blackheath; Mr. Westropp, Lisdoonvarna; Mr. Rushton Parker, Birmingham; Mr. Dunnett Spanton, Hanley; Dr. Thomson, South Yarra; Mr. Richards, Hastings; Mr. Walker, London; Mr. German, London; Dr. Taylor, Scarborough; Dr. Sloan, Glasgow; Mr. Crokery, Downpatrick; Dr. Macnaught, Greenock; Messrs. ## SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year.....£1 12 6 | Six Months .....£0 16 8

TO CHINA AND INDIA ..... One Year, 1 16 10

TO THE COLONIES AND UNITED STATES .. Ditto, 1 16 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET OFFICE, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

LONDON: SATURDAY, SEPTEMBER 9, 1882.

## ADDRESS TO STUDENTS.

## THE MEDICAL CURRICULUM.

THE conjunction of a sound mind with a sound body is an indispensable condition of the successful study and practice of medicine. A clear intellect and a quick understanding are indeed necessary, but they will not suffice. The study of medical science requires considerable mental powers; but medical practice has heavy bodily tasks that none but strong men can perform, and none but strong men should attempt. Without a sound constitution and robust health the medical student and practitioner will sooner or later find they must narrowly circumscribe their spheres of activity. The health-qualification is not sufficiently considered by some of those who enter the ranks of the medical profession. It is only when the constitution is undermined, the health broken, and the energies exhausted by the hardships, the exposures, the anxieties, and the constant application of mind and body under unfavourable and depressing conditions that its importance is fully appreciated. It is then often too late to correct the error. The whole life, training, aspirations, and interests are staked in the enterprise, and to be compelled to withdraw is an acknowledgment of defeat and failure. Those who are now contemplating starting on the medical career should assure themselves they are endowed with bodily strength and activity commensurate with the demands that are likely to be made upon them in after-life.

Next to a sound body, the qualification for the successful pursuit of the science and art of medicine is a cultivated understanding. In some degree this is provided for by a preliminary examination, but this security is not enough. The general education should be the best attainable, both as regards thoroughness and extent. By this we do not mean the student should have an elaborate acquaintance with any particular form or department of learning, whether classical or scientific, but rather that he should be carefully trained and disciplined in every useful, mental and moral exercise. Much has been said in favour of what is called "a university education" for all medical students; but experience has shown this is not an unqualified benefit. While it is desirable that every medical man should be an accomplished gentleman as well as a skilful practitioner, great scholastic attainments do not necessarily imply special aptitude for medical practice. Those who have obtained a degree in Arts before they begin medical studies have passed the time when they can readily apply themselves to the rudiments of their technical training, or have acquired an intellectual starchiness that prevents them from stooping to the fancied drudgery of such rudiments. Any youth of average talents, whose education is conducted by competent masters, may acquire an amount of general knowledge and mental discipline equal to the demands of any department of medical science.

It is, however, desirable that the student should have  
No. 3080.

correct notions of the meaning and object of education. In the subjoined sections, written by different eminent and experienced teachers, the medical novice will find many useful hints and suggestions as to the best mode of practically studying the various subjects embraced in the medical curriculum. He must, nevertheless, not be led astray by the belief that familiarity with any or all of these subjects will give him practical power. The medical education is almost wholly technical, though, unlike some other forms of technical training, it is capable of ultimately being transformed into culture. Despite the tendency of current opinions, it should not be assumed that education means mere knowledge, or learning, or the giving and receiving of instruction. It means rather, in MILTON's words, "that which fits a man to perform justly, skilfully, and magnanimously, all the offices, both public and private, of peace and war." The prevalence of the doctrines of the utilitarian philosophers has done much to foster false and erroneous opinions of the end and purpose of education. Knowledge, not wisdom, has become the approved end of education, and cleverness in examination rather than the skilful management of the affairs of life, the final test of success. The best minds have in all ages protested against this specious doctrine. RABELAIS, MONTAIGNE, MILTON, LOCKE, and others, have denounced it. "The greatest clerks are not the wisest men," said RABELAIS, and our COWPER differentiates the tendencies of these two schools in his lines:—

"Knowledge and Wisdom, far from being one,  
Have oftentimes no connexion. Knowledge dwells  
In heads replete with thoughts of other men;  
Wisdom in minds attentive to their own.  
Knowledge is proud, that he has learnt so much;  
Wisdom is humble, that he knows no more."

As education does not, therefore, consist exclusively or solely of the acquisition of knowledge, but includes the complete and harmonious development of all the mental and bodily faculties, the exercise and training of the natural senses should not be disregarded. In this age, when progress in applied science depends chiefly upon the elaboration of apparatus and instruments, when the conquests of therapeutics over pathology depend mainly upon the perfection of the physical aids to diagnosis, there is some risk of ruining the natural senses by the exclusive use of instruments. KANT foresaw this danger more than a century ago, and uttered a note of warning against it. The stethoscope, the thermometer, the sphygmograph, the ophthalmoscope, and the laryngoscope, have enlarged our powers of diagnosis, but it is doubtful whether they have extended our usefulness as practitioners of the healing art in a corresponding degree. Without these aids the modern practitioner is often helpless, where his forefather, prompted by the dictates of a trained experience, would have struck boldly and struck to good purpose.

However large the amount of instruction imparted in the medical curriculum may be, the medical student and practitioner who shall be worthy of their calling must be in a large measure self-taught. The student must see, hear, handle, think, and judge for himself. His knowledge and his experience must be organically assimilated, and not merely mechanically stored within his memory. Now, more than in any previous period, the student is in danger of too much didactic teaching, or, as LOCKE

would say, "of being magisterially dictated to what he is to observe and follow." Nearly three hundred years ago MONTAIGNE condemned excessive tutorship: "'Tis the custom of pedagogues to be eternally thundering in their pupils' ears, as if they were pouring into a funnel, whilst the business of the pupil is only to repeat what the teacher has said." This "thundering in the ears of pupils" may secure success in examination, but it will never bring that Knowledge which is Power. While then the pupil must in many things deliver himself up to the influence of authority, he must ever remember that he can only know through his own understanding. Though lectures and book-reading will do much for him they will not do all; they will not do even enough. The rest he must accomplish for himself. He must meditate upon what he hears and sees; he must reflect, test, and verify continually. There is no better way than diligent attendance on well-conducted class-examinations, self-questionings, and discourse with judicious friends. On this matter LOCKE, whose "Thoughts on Education" every one should read, has some wise words. "Reading," he says, "is but collecting the rough materials, amongst which a great deal must be laid aside as useless. Meditation is, as it were, choosing and fitting the materials, framing the timbers, squaring and laying the stones, and raising the building; and discourse with a friend (for wrangling in a dispute is of little use) is, as it were, surveying the structure, walking in the rooms, and observing the symmetry and agreement of the parts, taking notice of the solidity and defects of the works, and the best way to find out and correct what is amiss; besides that, it helps often to discover truths, and fix them in our minds as much as either of the other two."

#### ANATOMY.

b. In most cases the medical student will for the first time be brought into acquaintance with the real knowledge of a science by his study of this subject. To those who have had a practical experience of the methods and objects of scientific studies by a preliminary year's work at botany or comparative anatomy, the transition will be easy, and advice as to how to work is almost uncalled for. Steady application, constant work in the dissecting-room, and a keen desire to see for oneself and to verify the statements and descriptions of the best text-books are quickly developed when one has some prior acquaintance with the biological sciences, their aims and their methods. Students who have been fortunate enough to have secured this style of training will find no difficulty whatever in entering on their new work. The manipulative dexterity and the habit of close observation have already been acquired by them. With the student, however, who comes direct from a school, where the biological studies are omitted from the course of study, as is unfortunately still done in most schools, the case is different. Instead of passively imbibing the teachings of his master, he will now for the first time have to consider how to make the best use of the means at his command, so that he may verify the facts that are taught to him. His teacher no longer tells him with the weight of authority what deductions he must gather from the facts before him; he rather puts the facts forward, asks the pupil to see for himself that they are facts, and at most suggests or indicates what are the probable inferences which the student should draw therefrom. This is

the sole purpose of lectures on anatomy. A masterly arrangement of the facts, a precise and clear method in bringing them before the pupil, an obvious demonstration of every point on which any stress is laid, and an intimation of the importance thereof in the general scheme of nature, is the proper plan by which the interest and curiosity of every anxious and true student may be gained. The pupil is then urged on to examine these things for himself, and to form his own conclusions. In this way the true scientific spirit and the desire for real knowledge is fostered and assiduously maintained. The application of human anatomy to the details of practical medicine and surgery can only be laid before the student to be mastered by him at a late period of his career. It is therefore of the utmost importance to the young medical pupil that he should first learn how to observe and how to think. The practical outcome of the relations of his science to the needs of his future daily work should be carefully kept in the background until the general and more properly educational effects of his contact with the biological sciences and their methods have been allowed to exert their proper influence upon his mind. A beginner who wants to see the practical use of every detail of his scientific instruction will never attain to that breadth of view which should characterise the physician and surgeon, but will merely become an ill-educated, rule-of-thumb mechanic. A student should always be taught to strive first for the attainment of the true scientific mind, full of information, well-balanced in its inferences, and especially careful in the observation and arrangement of its facts before any attempt is made to come to a conclusion therefrom. The practical means for the cure and alleviation of disease will readily be mastered if their secondary importance in the true education of the medical man be clearly understood and appreciated. For the study of human anatomy, therefore, as of every branch of biological science, the lectures on the subject should be diligently attended, so that its aims and methods may be the more readily grasped and its due importance appreciated. It forms the real basis on which all the other sciences, such as physiology and pathology, are built; and without an accurate knowledge of its details, practical medicine and surgery must degenerate into the mere routine empiricism of the quack. The aims and methods therefore may be learnt from the lecturer; but for any knowledge which can be called real and valuable, the student must rely on his own assiduity and thoroughness in the dissecting-room. To become an anatomist, "he must dissect, dissect, dissect, always dissect." There is no royal road, no easy method. He may read, but reading can only tell him what he should see. He must see for himself if he would derive any benefit from his labours. He must clearly understand that books can only give him information, whilst from observation of and contact with the thing itself come real knowledge. The best guide that the student can use for this purpose is Professor ELLIS'S well-known Manual of Dissections. Its completeness and accuracy place it far above any of its rivals, although some of these are more attractive in style and more easily comprehended. The systematic text-books most used by students are QUAIN'S Anatomy, GRAY'S Anatomy, and WILSON'S Anatomist's Vade-Mecum. The last-mentioned was an especial favourite with the medical students of a former generation,

and the latest edition, whilst being well brought up to date, retains all the clearness and vigour of its predecessors. Its cheapness is another recommendation. GRAY'S Anatomy is undoubtedly the most popular text-book on the subject, and the excellence of its plates and the easy style in which it is written will always keep it in favour; but the really industrious learner will prefer QUAIN, which is the only work that will give him an insight into the broad domain of general morphology, at the same time that it places before him an accurate and detailed account of even the most minute structure in human anatomy. The histological portion of QUAIN'S Anatomy is the best *résumé* of modern knowledge that is to be found in our, and perhaps in any other, language. Many students purchase separate works on Osteology, but these are really unnecessary, although HOLDEN'S for its perfection of style and variety of illustration, and WARD'S for its minute accuracy, will repay anyone for the time spent in studying them. Having devoted two years to systematic descriptive anatomy, and having passed the primary examinations, in which this is the most important and most difficult of the subjects in which the student's knowledge is tested, he usually passes on to a study of medicine and surgery. It is at this point that a very grave and serious mistake is generally made. Anatomy is now given up, and the dissecting-room is forsaken for the wards. We would most strongly urge students to give up some portion of their third year to further dissections. It is at this period, and at this period only, that the practical bearings of anatomy on medicine and surgery can be properly learnt and appreciated, and it is because so few students dissect after their primary examinations that the study of anatomy degenerates into a mere cram, and fails to exercise its due and legitimate influence in the formation of the student's mind, and being always at his disposal in determining a point of diagnosis, settling a plan of treatment, or guiding him in the choice and presiding over the details of an operation. For this extra course no especial text-books have been written; but the student will gain much information from either BELLAMY'S or CHIENE'S Surgical Anatomy, whilst BRAUNE'S Topographical Anatomy and HOLDEN'S Landmarks are invaluable. It is much to be regretted that we possess no work on Applied Anatomy of first-class merit. Our Continental neighbours are far in advance of us in this respect.

#### COMPARATIVE ANATOMY.

The study of this subject is at present obligatory only on students for special examinations, such as the medical degrees of the University of London, and of the older universities, and the Fellowship of the Royal College of Surgeons. Undoubtedly the value of Comparative Anatomy as a means of education is enormously beyond what this very limited requirement might appear to indicate. This is strikingly apparent to teachers having experience of medical students, passing, as the great majority do, directly from the book work of school to the practical work of the hospital dissecting-room and wards. Considered in this light the subject is on a par with such sciences as botany and chemistry, cultivating the observing power, and teaching system and exactness. But it has the great additional merit that it affords an introduction to the earliest and probably most important study of the medical student—

human anatomy; and not only this, but it puts this study upon a broad and scientific basis, explaining and giving additional point to many facts which would otherwise be mere efforts of memory to him. For all these reasons the importance of this science to the student of medicine has been emphasised by some of our most celebrated teachers, and it is safe to predict that a more important place will before long be assigned to it by the various examining bodies, notwithstanding the crowd of subjects, and even of distinct sciences which now force themselves on the attention of the student of medicine. From what we have said it is apparent that the subject should be acquired by practical work, and this is rendered more imperative by the fact that notwithstanding the large number of good books before us, there is not one that entirely meets the wants of the student. On this account it is a subject, perhaps above all others, in which he must look for help to his own observation and to his teacher. If the Fellowship of the Royal College of Surgeons be his goal he should cultivate acquaintance with the museum, and there devote himself particularly to osteology. Admirable collections are found in the museums attached to some of the London hospitals, but if these are not available he will find everything that he can desire in the museum of the Royal College of Surgeons. It must be remarked that different examiners vary very much as to the amount of knowledge they expect from candidates. Indeed as matters stand at present we might parody a very familiar quotation, and say, "As many examiners so many degrees of examination in comparative anatomy," from the entire ignoring of the subject to a rigid questioning over a wide range according to the degree of importance which the examiner attaches to the subject, or possibly the extent of his acquaintance with it. In such case it is difficult to recommend books. The student can use either very elementary books—such as, for example, the Zoology of the London Science Class-book Series, or he can extend his studies through NICHOLSON'S Advanced Text-book, or Manual of Zoology, to the admirable Osteology of Mammalia of FLOWER. Students for the Preliminary Scientific Examination of the University of London are confronted by a similar difficulty. HUXLEY and MARTIN'S Biology is most admirable, but it includes only part of the requirements of the schedule. For the anatomy of the animals not described in it, it is necessary to consult the difficult and somewhat obscure work of ROLLESTON on Forms of Animal Life, and HUXLEY'S Anatomy of Vertebrated and Invertebrated Animals. NICHOLSON'S books on Zoology, though in some respects behind the time, will furnish the classification, unless the student has the time to consult in this respect the previously mentioned works of HUXLEY on Vertebrated and Invertebrated Animals. GEGENBAUR'S Manual of Comparative Anatomy will place his knowledge of the science upon a wider and more scientific basis. But even now the student has not found all he wants, and we repeat that he must depend to a considerable extent upon his teacher, and above all things upon his own dissections.

#### PHYSIOLOGY.

The importance of a knowledge of anatomy as a sure foundation for the practice of medicine is equalled, if not exceeded, by that of physiology. The two subjects are

complementary to each other, one speaking of form, and size, and relative arrangement of parts, the other of their use and purpose; whilst histology and physiological chemistry occupy a kind of intermediate position, the former dealing with the minute structure of the different tissues; the latter showing their composition and the changes which occur in them as the result of their activity. The wider and more accurate the knowledge of these subjects possessed by a practitioner the more competent does he become to discharge the duties of his profession with advantage to his patients and satisfaction to himself. And just as no man dare undertake to cut down upon an important artery when injured, with the view of applying a ligature to it, without a knowledge of its course and surroundings, derived from dissection, so before a physician can hope to treat indigestion or pneumonia, or albuminuria with success, he must be acquainted with the natural processes which are carried on in the stomach, lungs, and kidney. It cannot, however, be too strongly impressed on the student that the several organs of the body do not act in an isolated and independent manner, but that there is the closest and most intimate connexion between them, that all work together to preserve the body in health, and that none can be disturbed or impaired without affecting the rest. To appreciate this the student should in the first place acquire a sound general knowledge of the whole subject, without entering into details; and this may be obtained by careful study of one of the smaller text-books before attempting to master such large treatises as those of FOSTER, CARPENTER, or KIRKES. A large number of men, there can be little doubt, lose themselves in such efforts, lose their interest in what is really an extremely interesting subject, and, instead of acquiring a general grasp of the functions of the body which may be serviceable to them in after-life, endeavour only to obtain the answers to those odd and exceptional questions which are now and again put by all examiners, and ignorance of which is supposed to be fatal to success in examination. In truth, however, the failures that take place at the Primary Examination of the College of Surgeons, which attain so large and discreditable a proportion, are far more attributable to ignorance of elementary facts than to want of knowledge of details. The examiners complain that the candidates are insufficiently grounded; that whilst they are familiar and their memories temporarily burdened with many minute and unimportant facts, they are ignorant of large and general principles that are of constant application. The object of the courses of lectures that are delivered at every school is to give the student this general view of the whole subject; and he is the best lecturer who can most clearly impress on the minds of his class the principles of his own department of knowledge, and show its connexions with the medical art. We strongly recommend the student, therefore, to read some rudimentary work, even if it be no larger than FOSTER'S Primer, straight through. He will thus obtain a bird's-eye view of the whole subject; and though, of course, the knowledge thus obtained will be insufficient to carry him through such an examination as that of the College, yet it may certainly be said that if its contents were thoroughly mastered and assimilated, many a man who is now rejected would pass. When he has learned

these well he may read through one of the larger works, always remembering that, if possible, he should do some practical work; at nearly every school arrangements are now made for teaching histology and the rudiments of biological knowledge. Let him devote his energies to the acquirement of such information; a few shillings will suffice to provide him with the necessary instruments, and he will soon find that the knowledge gained from practical work is a hundred-fold more suggestive and improving, as well as far more firmly imprinted in the memory, than the most carefully written description by the best microscopist or physiologist. To aid him in this he may take the excellent little Manual of Histology by Dr. HARRIS and Mr. D'ARCY POWER, and when he has fairly worked through this he need fear no examiner, and is in a position to apply the facts he has acquired to the investigation of disease.

#### CHEMISTRY.

The study of chemistry is still commonly commenced in the medical school. It is unfortunate that this should be so, for the press of other work leaves but little time for the cultivation of so enormous a field. The applications of chemistry to physiology, to medicine, and to hygiene increase each day, and require more and more of general scientific knowledge. Probably no two lecturers follow exactly the same order in teaching chemistry; but it may safely be assumed that a good many of the earlier lectures will be devoted to theoretical matters, such as the laws of chemical combination and the molecular and atomic hypotheses. To these subjects the closest attention should be given, and we cannot too strongly urge on students the importance of not missing any of the earlier lectures. To miss one is often to lose the clue to those which follow. Little repetition is possible in a course of lectures, and it frequently happens that a student who has missed the exposition of some important doctrine, such, for example, as the law of gaseous volumes, with its attendant hypotheses, will find his comprehension of the whole subsequent course marred in consequence. The law which we have cited as an illustration is indeed one of the most important in chemistry, and governs the whole theory of the science. It presents the first real difficulty to the student, and may be described as a *pons asinorum*, which many students never really pass. In this part of the course the simpler chemical calculations must be mastered. They will be explained in lectures, but can never be acquired without the patient working out of a good many problems. Problems of this kind occur in almost every examination. Thus students are constantly required to calculate the volume of gas yielded by a certain weight of material, to find the weight of an element present in a given weight or volume of a compound, or to find from the observed volume of a gas at one pressure and temperature what its volume would be at another pressure and temperature. Apart from the practical value of such calculations, they cannot be worked without sound theoretical knowledge, and are, in fact, the best tests for its presence. After the six months winter lectures follows the three months' summer practical chemistry course. The main object of this course is to enable the student to perform simple chemical analyses without book. But the diligent student makes it the opportunity of applying the book knowledge which he has

acquired at lectures and by study, and finds that every test he uses illustrates and confirms his old knowledge. He should by no means be satisfied with finding out the name of the substance given him for analysis. He should master every reaction, and should in every possible case write out the equation which shows the nature of the chemical change involved. Above all, let him remember that when he goes up for examination no book or written paper will be allowed. As soon as he understands the course, let him strive to learn it. He can thus subject himself to a continual practical examination, with the advantage of being able at every stage to correct his own errors and supplement his deficiencies. The number of text-books on chemistry is so great that recommendation is somewhat difficult. Much depends on the student's previous knowledge and on the time he intends to devote to study. Each teacher knows the books suitable to his course, and it is better, perhaps, to leave the selection to him.

#### PHYSIOLOGICAL AND PATHOLOGICAL CHEMISTRY.

In spite of the disparaging terms which such eminent clinical teachers as GRAVES and TROUSSEAU have spoken of the aid chemistry can afford to medicine, this science, as applied to physiology and pathology, has made definite progress during the last quarter of a century, and has now become a recognised branch of medical education. The discredit into which chemistry fell with practical physicians was no doubt owing to the fact that many of its advocates at an earlier period advanced theories based on insufficient observations, which, when brought to a practical test of the bedside, were found to be fallacious or inconclusive. This, however, can no longer be urged as a reproach, except in the case of a few enthusiasts and visionaries, and year by year we find a steady increase in the number of sound reliable observations, which are of material value in elucidating the nature of various physiological processes, and of aiding in the diagnosis and treatment of disease. Take, for instance, the physiology of digestion, with regard to which Professor EWALD justly remarks, the brilliant discoveries of chemical facts "have led to the attainment of new general points of view, have much elucidated its aspect, filled up many gaps, and turned the current of investigation into quite new channels." It is only necessary to enumerate a few of the discoveries: the action of the various ferments on the special food stuffs; the determination of the true nature of the acid of the gastric juice; the establishment of enormous influence the pancreatic secretion has on the digestive process, with its triple action on albumen, starch, and fat, together with the chemistry of its peptones; the destructive decompositions of one of these—hemi-peptone—which throw a light on the probable antecedent of some portion of the urea existing in the blood; to say nothing of the discovery of glycogen in the hepatic cells, and the conversion of this substance into glucose; discoveries which have given the pathology of diabetes, previously wrapped in obscurity, quite another aspect—to show how important has been the aid chemistry has bestowed on medicine in one field of observation alone. The same may be said almost with regard to urinary pathology. Here progress has been more marked in settling disputed points and demolishing unsound theories than in making fresh discoveries. Many im-

portant chemical facts, too, have been established bearing upon alterations in the blood and tissues in health and disease, which are of practical utility. But, apart from the now recognised value of chemistry as an aid to the study of physiology and medicine, there can be no doubt of the advantages derived from a practical study of physiological chemistry. Not only has a student the advantage of actually seeing and handling the substances about which he hears and reads so much, but he attains a knowledge of various analytical procedures that is in itself valuable as a scientific training in accuracy and method, and which is likely to prove of practical utility in his professional career. The works recommended are the Handbook of the Physiological Laboratory, edited by Dr. BURDON-SANDERSON (Churchill), and Professor GAMGEE'S Text-book of the Physiological Chemistry of the Animal Body (Macmillan). These works are designed more for the use of those who intend to make the subject almost an exclusive study; whilst for the ordinary medical student, the concise Demonstrations in Physiological and Pathological Chemistry (Bogue), arranged by Dr. RALFE, will supply the practical requirements for the pass examinations of the College of Surgeons and the College of Physicians.

#### BOTANY.

Lectures and practical instruction in botany form a part of the curriculum in the first summer session. This subject was at first introduced into the course of studies in order that the practising apothecary might be able to collect his own herbs; this use of botanical studies has now almost passed away. The study of vegetable growths as a department of biology, and as an aid to the study of physiology and pathology, is, however, well worthy of a permanent place in our curriculum. Botany should be studied for the assistance it affords as a science dealing with simple and elementary bodies, and because it throws light upon some of the general principles of growth and illustrates the principal processes of reproduction among living beings. Botany, if properly studied, will add much to the student's accomplishments and mental culture, for it is the best example of a systematic science to be found in the medical curriculum. It affords opportunities of describing specimens, it encourages accuracy of observation, exercises powers of classification, and stimulates the imagination. The student should for his own sake not neglect this subject, but look upon it as a science dealing with simple living organisms subject in many points to the same laws as the animal frames, but presenting no structural nerve system and no general circulation. Thus viewed the science has a bearing upon comparative anatomy, there being no distinct boundary between the animal and vegetable kingdoms, so that many points of great philosophical and analogical interest are illustrated by the facts observed in the study of the two sciences; many of the properties of elementary animal tissues may be studied in plants—e.g., the movements of cells, the movements in cells, the effects of light, heat, electricity, and gravity. Again, a knowledge of botany is essential to the successful study of materia medica and forensic medicine; further, no medical diploma can be obtained without passing an examination in botany. For the university degrees in London and most other places the

student is required to give practical descriptions of floral specimens. In training for this exercise, let every plant and flower be looked upon not simply as something to be identified, named, and classified, but as a living structure of which every part has its meaning, and every shape and touch of colour its particular use. In examining a specimen always take notes of the points observed. The flower may first be examined as to its structure, the number, union, and arrangement of all parts, and it is well to record these particulars in some form of schedule; that given in Professor OLIVER'S book is very useful. In this kind of work information is easily obtained from any of the text-books or floras. Let the student, however, never rest satisfied when examining a flower without endeavouring to obtain an insight into the use of each part in its structure, shape, and colour. In this kind of study much help will be gained from Sir JOHN LUBBOCK'S little work, "British Wild Flowers in Relation to Insects." When, as must frequently be the case, he fails fully to understand a specimen, let the student note the limits of his knowledge and his failure, thus he will learn to look wisely upon the unknown, to train his mind, and to be patient. A good opportunity is thus afforded early in the course of study for the exercise of the imagination within due limits, and for the exercise of the healthful aspiration, to try some process of original thought. The knowledge of a few of the natural orders of plants is necessary, and is required by the Examining Boards. This kind of knowledge is best obtained by systematically observing, describing, and comparing a few plants in each of the specified orders. Any London student can obtain a free order of admission to the Royal Botanical Society's Gardens, Regent's-park, by applying to his lecturer; in these gardens all the plants are arranged according to the Natural Orders, a flower bed to each order. This method of study is more useful, and is certainly pleasanter, than getting up by rote a list of the characters of the orders from a book, and this knowledge well obtained is not easily lost. BENTHAM'S Flora contains an analytical key, and by the aid of such a book any plant being taken its order can easily be determined and the specimen compared with the description of the plant in the Flora. This is excellent practice and pleasant work. Personal acquaintance must be made with the more important of the medicinal and poisonous plants, and their orders should be remembered. We would advise the student to study systematically a few orders, and a moderate number of floral specimens in each order with the aid of the Flora. Wild flowers only should be used, as those long cultivated artificially are apt to present variations. As to the use of books in study, there are many on systematic botany, fewer giving original physiological work. Professor OLIVER'S Lessons in Elementary Botany is a very useful small work, embracing most sections of botany with descriptions of some orders. A further account of the structure and physiology of plants will be obtained from MacNab's little work, 150 pages, in the London Science Series. This author has also issued a similar work on the classification of plants. A Text-book of Botany, by PRANTL and VINES, gives a very good account of structure, physiology, and classification, and is very useful to candidates for degrees. As one of the most useful works on descriptive and systematic botany we strongly recommend Professor BENTLEY'S Manual of Botany

as very complete and well illustrated. ASA GRAY'S Structural Botany is very trustworthy; only one volume of a series of four has yet appeared. The best work on structural and physiological botany is the English translation of SACH'S Text-book of Botany; it is complete, original, well illustrated, and a trustworthy authority to the student reading for honours. Sir J. HOOKER has written a little primer, which is a useful introduction to botanical study. BALFOUR'S Class Book is a well-illustrated compendium, fully illustrated, but rather bulky. To those who desire to become further acquainted with the biological aspects of botany, we strongly recommend the perusal of CHARLES DARWIN'S works. The Movements of Plants is a book affording most interesting proofs of the sensibility and brain-like action of some vegetable tissues, and their exquisite sensitiveness to light, touch, and gravitation, showing the usefulness of these properties to plants. "The forms of flowers" and "cross fertilisation" give beautiful examples of special adaptations of form and properties, and illustrate the laws of inheritance and cross-breeding in producing variations in a species. Useful Floras have been written by Sir J. HOOKER and BENTHAM.

#### MATERIA MEDICA, THERAPEUTICS, AND PHARMACY.

It is often supposed that materia medica is a dry subject. This is a mistake, for if taught by a lecturer well acquainted with the physiological action and therapeutic uses of drugs it is one of the most interesting subjects in the whole of the medical curriculum. It has this advantage, too, that it is a thoroughly practical subject, and much of the student's success in the profession he has chosen must depend on his skill in treatment. Materia medica demands a knowledge of many other subjects, and no one can hope to attain eminence in this branch of his profession who is not a fair botanist, a good chemist, and a practical physiologist. Materia medica is not a subject that can be learnt from books, the student's knowledge must be practical or it is valueless. It is useless for him to read about aconite, belladonna, and digitalis if he does not know the monkshood, deadly nightshade, and foxglove when he sees them. Many of our most valued remedies are obtained from plants that grow in the fields and by the wayside, and there is no excuse for a student who fails to make himself acquainted with them. Even in London there is no difficulty, for they are all grown in the Botanical Gardens, Regent's-park, and students' tickets for the purpose of study are always readily granted during the summer session. It is essential that the student should have access to a good materia medica museum—without this he can do nothing. He must examine each and every specimen for himself, and he must learn to know them not only by their general characters but by taste and smell also. There are certain drugs which are instantly recognised by their smell—prussic acid, acetic acid, ammonia, chloroform, camphor, cajuput, and assafoetida for example, and these the student should be familiar with, for he is pretty sure to get them at some of the examinations. He should endeavour to make a materia medica collection of his own, a collection that should contain specimens of at all events all the common drugs. Materia medica cabinets may be purchased, and some of them are excellent, but there is no collection so use-

ful to the student as that which he forms for himself. It would be well to study practically the physiological action of some of the more common alkaloids, but there are many difficulties in the way, and on this point, as on many others, the lecturer will have to be consulted. The subjects most worthy of illustration are the action of strychnia on the spinal cord, and of muscarine, atropia, aconitia, and digitaline on the heart, although of course the list might be almost indefinitely extended. The student must not neglect to avail himself to the utmost of his three months' instruction in pharmacy. It does not matter what his special department of practice may be in the future he cannot fail to learn much from a good dispenser. The student must not suppose that his studies are to be limited to officinal remedies, on the contrary, many of our most valued therapeutic agents find no place in the British Pharmacopœia. With regard to books, there is less to be said than might at first sight be supposed. There is no dearth of works on materia medica and therapeutics, but many of them are quite unsuited to the wants of students. Take PEREIRA, for example, or NÉLIGAN'S Medicines, or the National Dispensatory of STILLÉ and MAISCH. These are monuments of industry, replete with information of all kinds, but they are too large to read, and are intended as works of reference, and not as text-books. Another work quite unsuitable for students is the British Pharmacopœia. It was never a good work, and is now quite out of date. One of the best students' books on materia medica and therapeutics is GARROD, which has been popular with many generations of students. It is a good book, although somewhat behind the times as regards therapeutics. WHITLA is a work published only this year, but it is accurate and trustworthy, and will prove a formidable rival to some of the older works. THOROWGOOD is used at some of the schools, but it is too limited in its scope to be of much use to students. On therapeutics proper we have several excellent treatises. RINGER is thoroughly practical, and is still a good book, although there has been a considerable falling off in the last edition. PHILLIPS is in two large volumes, and is as yet incomplete. BARTHOLOW is an American work, but it has found favour in this country, and is frequently used both by students and practitioners. FARQUHARSON'S Guide to Therapeutics is well arranged, and is an excellent work in every way; it is small, but contains a great deal of useful information. For the physiological action of drugs there is nothing to equal WOOD. It is an advanced book, and a student would be ill-advised to begin with it; but for the higher examinations or for honours it is without a rival. There are several other works which may be found useful from time to time. For the history of drugs, for example, the Pharmacographia of FLÜCKIGER and HANBURY is admirable. The syllabus of HARVEY and DYCE DAVIDSON is a list of drugs and their preparations, printed in different sized type, according to their importance. MURRELL'S "What to do in Cases of Poisoning" will be found useful to students preparing for examination either in materia medica or forensic medicine. For hints on prescription writing PEREIRA'S *Selecta à Præscriptis* is well known. MORSHEAD'S tables of the physiological action of drugs may sometimes be consulted with advantage, and BRUNTON'S tables of materia medica are useful. The recently published Pharma-

copœia of the London Hospitals will be found of use to advanced students.

#### OBSTETRICS AND GYNÆCOLOGY.

The second summer session is the most convenient to attend the lectures on midwifery and diseases of women. Attendance on women in labour should not commence until the lectures on natural labour have been completed, and the mechanism of natural labour, together with the diagnosis of the various presentations, has been thoroughly mastered. It is best for the student not to attend his first case alone, but in company with the assistant to the obstetric physician or with a senior student who has already completed his attendance on midwifery. In this manner he will be greatly aided in recognising the conditions present in the case before him, and in carrying into practice the details which are known to him as yet in theory only. The diseases of women form now a far more important department of medicine than they did thirty years ago, and the means of acquiring a practical acquaintance with them at the medical schools are far more perfect. The student would but waste his time, however, were he to devote himself to the study of them during the earlier part of his career. The successful study of any special branch of medicine requires an acquaintance with general pathology and medicine, and this is especially true of the diseases of women. A knowledge of them does not consist in an acquaintance with uterine mechanics simply, for scientific gynæcology, like other departments of medicine, is based on the anatomy, physiology, and pathology of the organs concerned, and also largely upon general pathology. The student who devotes himself to their study before he has made himself acquainted with the other subjects named will acquire but a very imperfect, narrow, and inaccurate notion of the diseases of the female pelvic organs. The fourth winter and summer sessions will prove the most profitable period for the study of this branch, as well as of other special branches, of the healing art. It is best for the student to obtain a good book and study it thoroughly. It is folly to get many books and read them in a cursory manner; this will only lead to confusion and want of definite impressions. The best books on midwifery are the works of LEISHMAN, LUSK, and PLAYFAIR. On diseases of women, the works of BARNES, WEST, and GRAILY HEWITT, for those who read for the London University. Of the smaller works GALABIN'S and ATTHILL'S are the best.

#### MEDICINE.

There is some difference of opinion as to the time in the student's career at which he should enter upon the study of medicine proper. This is unfortunate, as it often leads to the student choosing his own time, and seeking too early to become acquainted with a subject for which he has not then received the necessary preliminary training. Doubtless this difference of view has arisen out of the old apprenticeship system, where the first step taken by the future medical student was to become acquainted with details of practice, the *rationale* of which he could not have been expected to know, and although common sense and the division of examinations into "primary" and "pass" have, to a certain extent, brought about salutary changes in this respect, the student is still too much encouraged to follow the old way, and to enter at the outset upon work which more fitly comes

ater in his career. The real profitable study of medicine, indeed, should not be commenced until the foundations of anatomical and physiological knowledge have been solidly laid, with the exception of certain preliminary matters to which we shall presently allude. The first-year's student would then be well advised not to encourage the too-natural desire to be brought into actual contact with patients, nor to try to understand the principles of practice. He is obviously unfitted for this work, and it is sheer waste of time to attempt to follow it. Let him confine his whole energies to mastering the details of such subjects as anatomy and physiology, botany and chemistry, in which he will find scope enough to exercise all his faculties. But if at the same time that he is doing this he hampers himself with hospital work, he will do it at his cost, and find out his mistake when the examination day arrives. The position taken by those who maintain the contrary is readily understood. If they do not actually desire a return to apprenticeships, they point to the brevity of the curriculum, and the importance of devoting every portion of time that can be spared to working at medicine, which, after all, takes the chief place, being that which will be the subsequent life work. At least, they say, let the young student pick up what crumbs of information he may from daily attendance in the wards or out-patient room, forgetful of the inevitable fact that information obtained thus is like grain scattered on an untilled soil, and the result is, either to give the student crude and imperfect notions, or to fill him with the idea that he knows far more than he really does. Many a student has been spoiled for subsequent work when it comes to him by having in this way obtained a false estimate of his knowledge. He thus comes to scamp the elementary principles of medicine, and fails to obtain a real grasp of the subject. We do then distinctly discourage the practice, still so common in many hospitals, of appointing first year's students to clerkships in the out-patient department or elsewhere. The only good they can really reap from such appointments is that of increasing their physiological knowledge. They may seize the opportunity given them of learning such normal facts of respiration and circulation as can be observed by methods of physical examination, may learn to define the surface-limits of organs, to become familiar with the use of the ophthalmoscope, laryngoscope, and sphygmograph—solely with reference to healthy conditions:—these and other matters they may pursue with profit; but it is too much to expect of them to understand the departures from the normal that constitute disease, or to appreciate the methods employed in treatment. Starting, then, with the assumption that the study of medicine is intentionally deferred until after the anatomical and physiological courses are passed through, let us briefly glance at the nature of the work set before the student in this department. As in other subjects the work falls under the heads of theoretical and practical, or, as may be more fully and correctly stated, under: (1) Lectures, systematic and clinical; (2) tuition, or clinical demonstration; (3) clinical observation; (4) reading. Upon the first two of these methods of study there is no need to dwell at length. The systematic course of lectures on the principles and practice of medicine is a winter course, and will therefore be attended by the student in his third year, by which

time let us hope he will have come to appreciate the value of lectures as a means of instruction. Of course it is understood that regular attendance and attention are paid to these lectures—otherwise they may just as well be omitted altogether. The student will never regret paying the closest attention and taking full notes of what he hears, for the value of a lecture lies in its presenting him with the information in a concise and clearly comprehensible form, a guide to his reading, and an analysis of facts which he is unable to get in any other way. Clinical lectures owe their value to the fact that the physician deals with cases which the student has had the opportunity of seeing, and in the lecture-theatre advantage is taken to dwell on the lessons derived from the study of facts of observation more fully than is possible by the bedside. Under the head of tuition in medicine may be included clinical teaching as distinct from the personal practical duties done by the student in his capacity as clinical clerk. Now instruction upon disease is of course most valuable when the pupil sees before him the living example of the disease upon which he is being taught. There are many ways in which this part of his work is carried on. There is the physician's regular visit to the wards for the purpose of seeing and treating his patients. Students should avail themselves of the opportunity of accompanying the physician on his rounds, even if he do not spend much time in actual teaching. He is sure to drop hints that are of value, and to point out facts of importance as he passes from bed to bed. Besides, the attendance on the physician enables the student to watch the cases in progress. Still more useful to the beginner is the class tuition which is so necessary a feature in good clinical teaching. We hold that clinical teaching should be planned systematically, and that starting from elementary instruction in case-taking, in methods of physical examination, &c., to classes where students are questioned on all points concerning the diagnosis and treatment of any special case, he comes to case-reporting; in this we have a system of clinical education that is ample and efficient. It is not the mere presence of the student in the wards, forming, perhaps, one of a group of thirty or forty gathered round the physician at the bedside, it is not the simple fact of his listening to the remarks let fall by the physician, valuable as these may be, that profit him most. He must learn how to examine the patient for himself, how to inquire into his previous history, how to report on his progress, and how to discuss diagnosis, prognosis, and treatment. All that tuition and demonstration can do is to put him on the right road in this personal research, to correct his errors, and to encourage his pursuit of knowledge. Thus we pass naturally to the third and really the most important branch of medical training—personal clinical observation—which of course is inseparably blended with clinical teaching of the "how, why, and what," to observe by the bedside. Besides joining the class of case-reporting there is another way in which the student is brought into personal contact with the patient—i.e., by holding a clinical clerkship. In this office he is attached to the ward service of one of the physicians, and should be directly under the control and guidance of the house-physician. The clinical clerk has many duties to fulfil, and if he is really desirous of working well, not only for the sake of knowledge but for

the approval of those under whom he works, he should be punctual and diligent in the performance of his duties. Like every other duty, it is possible to perform these in a perfunctory manner, but no one should take a clerkship unless he is resolved to let nothing else preoccupy him. He will find that in taking the history of his cases, in recording his daily observations of the case, or those of the house-physician, in attending the physician's visits and adding the notes dictated by him, in examining and analysing urine, blood, sputum vomit; in taking pulse-tracings, chest measurements, electrical observations, &c., as directed—he will find the whole time not required by lectures completely filled up. He should moreover utilise his cases as a means of increasing his knowledge of disease,—and it is most useful to that end to “read up” in his books the description of diseases of which they are examples. It is perhaps impossible for a man to hold such an office without learning something, but it rests with himself in large measure to make that knowledge wide and full. Before entering upon ward-duties such as these, the student will not find the time lost if he previously hold a clerkship to the out-patient department physician. The duties there demanded of him are less exacting, but properly utilised the post is very valuable, and we would advise all to hold it. This may be the proper place to speak of attendance in the out-patient department. There is so much to be seen and learnt there that the working student should make a point of being regularly present every day at one or other of the clinics. He should also not fail to regularly attend the special departments, such as those devoted to diseases of the skin and throat, where he learns so much that will be practically of value to him hereafter in the diagnosis and treatment of these affections. In all this work he will find it of great utility to cultivate the habit of note-taking, for the memoranda he then makes will serve him in good stead afterwards. Further, we would earnestly impress on the student not to be content with simply listening to what is told him, but to use every opportunity to inquire for himself—to question frequently when he is in doubt, and to satisfy himself that he really does see, hear, and understand what is pointed out to him. The more trouble and pains he expends in this the most fruitful time of his career, the sounder will be his knowledge, and the less reason will he have to fear examination-tests; or, what is worse, to have recourse to those unnecessary “cram-books” which he should resolve never to have recourse to. The culminating point of the student's hospital career, that which it should from the first be his object to aim at, is the holding a resident office. It only falls to a minority to fill these posts, but none who have held them can deny their great educational value. The duties of a hospital house-physician are to take daily notes of the cases entering his wards, and to be responsible for the treatment of them in the absence of the physician. In proportion as his previous clinical training has been full and exact, so will he make a good house-physician. It is his first introduction into the real serious business of his life, and the more he realises this the more thoroughly will he apply himself to his duties. Usually such offices are held after a medical qualification has been obtained, so that it may hardly be necessary to mention them here, except for the opportunity it gives us

for recording our emphatic belief as to their importance and value. We have left the subject of reading to the last, and have not much space to devote to it. Nor is it easy to single out particular works for study, especially as so many that are excellent for their purpose exist. The object of reading, is to supplement the instruction of the lecturer and tutor, to gain information upon methods of investigation, and to aid the student in his ward note-taking, &c. We cannot do better than recapitulate what has been said previously on this head in THE LANCET on similar occasions:—

“*Medicine.*—General: Tanner, Roberts, Bristowe, Carter, Charteris; Aitken, Niemeyer, Flint, Watson; Reynolds, Trousseau. *Nervous Diseases*: Wilks, Charcot, Althaus, Hammond, Bastian, Rosenthal, Gowers. *Diseases of the Heart*: Walhe, Balfour, Fothergill, Hayden. *Diseases of the Lungs*: Walshe, D. Powell. *Diseases of the Kidney*: Roberts, Dickinson, Stewart, Johnson, and Beale. *Diseases of the Liver*: Murchison, Habershon. This long list by no means includes all the works which may be selected from, nor do we wish to imply that the student should have to consult one-fourth even of the above. It will be necessary for him to procure one text-book, and the following brief hints may guide him in his selection:—Each has its own peculiarities. That of Dr. Tanner may be mentioned the first, because it has been longest in the field, and also because it is fully sufficient for most purposes; it is eminently practical. The handbook of Dr. T. F. Roberts is, however, perhaps the most useful, and abounds in information supplied in a thoroughly systematic manner, although from the very extensive range travelled over, the subject is necessarily condensed, and the book therefore no light reading. It is pre-eminently a student's book. The work of Dr. Bristowe is more original, and is valuable especially in its pathological portions, and in the admirable account given of diseases of the nervous system. Dr. Aitken's ‘*Outlines*’ are also good. But for a work which is both pleasant in the reading and valuable for its suggestiveness, the text-book of Professor Niemeyer takes the front rank. Certainly no candidate for the higher examinations should fail to read this book, and to carefully study it; for although in some sections it hardly comes up to the standard of some English authorities, yet, as a whole, there is no work like it. Dr. Flint's work has obtained a wide and deserved reputation, not only in America but also in this country. Dr. Alfred Carter has recently published a useful manual for students, and a still smaller work is that of Dr. Charteris. Nor should Dr. Watson's famous book on the ‘*Principles and Practice of Physic*’ be omitted, for many an hour may be passed both profitably and with pleasure in the perusal of these classical lectures. Those who intend taking high degrees, such as the M.D., should read much of the ‘*System of Medicine*,’ edited by Dr. Reynolds, and the time would not be wasted in the perusal also of several of Trousseau's admirable lectures on Clinical Medicine, translated by the Sydenham Society. Such candidates also would do well to read the monographs of Dr. Murchison on Diseases of the Liver, or those on Diseases of the Kidney by Drs. W. Roberts, Grainger Stewart, or Dickinson; and also to consult Dr. Walshe's works on Diseases of the Lungs and Diseases of the Heart, or the lectures of Dr. Balfour on the last-named subject. On Continued Fevers, there is no work comparable to Dr. Murchison's treatise. On Diseases of the Nervous System there are the larger works of Rosenthal, and Hammond; but the lectures of Dr. Wilks, and those of Charcot, which have been translated by the Sydenham Society, may profitably be read. Dr. Bastian's lectures on Brain Diseases and Dr. Gowers' lectures on Diseases of the Spinal Cord should prove of great use to the clinical student, for whose

needs we may now mention some works that have been specially written for aid in bedside observation :—

"*Clinical Medicine*: Da Costa, Finlayson, Fenwick, Tanner, Gee, Barclay, Warner. *Urine Analysis*: Legg, Tyson. *Ophthalmoscopy*: Browne, Jackson, Gowers, Clifford Allbutt. The first-named, with that of Dr. Da Costa, is of the highest class. The handbook edited by Dr. Finlayson is very complete of its kind; Fenwick's work is smaller, but has been much in use, whilst the subject of 'physical signs' in chest disease is admirably treated of in Gee's little manual on Auscultation and Percussion. To the clinical ward clerk the manual by Dr. F. Warner will be found of considerable utility. As aids in the analysis of urine, Dr. Legg's and Dr. Tyson's works are excellent. We have added four works on Ophthalmoscopy; the first is a guide to the use of the ophthalmoscope, which the beginner will find of great service; but the senior student will be repaid by studying the excellent work, which includes an atlas, by Dr. Gowers, or the book by Clifford Allbutt on the same subject. For reference, Liebreich's plates, or those of Jaeger, may be consulted.

"*Dermatology*.—Living's *Diagnosis and Treatment*, Fox's *Epitome*, Duhring, Malcolm Morris; Tilbury Fox, Neumann (Pullar's translation). *Atlases*: Tilbury Fox, Duhring. The student will find ample information within a small compass in the first-named works. Duhring's book is not so well known in this country as it deserves to be, and Neumann's is especially rich in cutaneous pathology."

#### SURGERY.

The fact that by the regulations of the Royal College of Surgeons a student is required to devote a portion of each year of his curriculum to the study of surgery is in itself sufficient proof of the great importance attached to this department of knowledge. It is not our desire to discuss the wisdom of this arrangement. In part it rests upon a misconception, and is due to the survival of notions which were proper only when surgery was not a science. When there were no general principles to fall back upon as a guide to practice, it was necessary for the practitioner to become acquainted in his student days with as many as possible of the various phases of surgical injuries and disease, and multiplied opportunities of observing both out-patient and in-patient practice were rightly insisted on. The special importance of a good knowledge of surgery lies in the fact that it may be required of any practitioner without notice to act promptly in emergencies; and also because surgical treatment has far more influence upon the course of injuries or diseases than medicinal treatment, and errors either of omission or commission are of greater import. But now that surgery is a science the student's chief aim should be to understand and thoroughly master the principles of that science which will serve him in the varied cases afterwards coming under his notice. There is no distinction between a "practical" and a "scientific" surgeon, although those ignorant of science are wont to try to conceal their ignorance by vapid exaltations of the merely mechanical arts of a surgeon. No one can now justly lay claim to the title of surgeon who is not first scientific and then skilled in the application of scientific knowledge. The essential preliminaries to an intelligent study of surgery are a sound knowledge of anatomy, physiology, and pathology. The attempt is sometimes made to apportion to each of these sciences their respective values, but no greater error could be committed. They are so allied, so intimately connected, so interdependent, that

the lack of one cannot be compensated by excess of either of the others. The mechanical and especially the operative parts of surgery are so attractive to most students, that it is especially necessary to insist upon the fact that surgery is a science, and not a mere empirical art. To learn how to adjust a splint, or how to perform kelotomy, is not to be fitted to treat a broken leg or a strangulated hernia. Not that the practical application of surgical knowledge or manual skill is of minor importance. Advancing science enables us to understand more and more clearly the importance of skill in even the most trivial operations. And here we are led to point out that the department of "minor surgery," as it is usually and incorrectly called, is one which demands the student's very careful attention. Apart from the fact that it is in daily use, and that every practitioner requires a knowledge of it, there is the consideration that success in surgical treatment depends chiefly, and in very many cases entirely, upon these "minor" details. The dressing of wounds, for example, comes under this heading, and there is nothing which more affects the results of surgical practice than a knowledge of the principles of the healing of wounds, and of the best modes of securing it. To point out the essential unity of medicine and surgery is to repeat an "oft told tale," but is none the less important, for it is a fact that is only too often forgotten by both teachers and practitioners. We would urge the student, then, to endeavour to study surgery purely as a science, to lose no opportunity of acquainting himself with the facts of surgical pathology, and of the bearings of anatomy and physiology upon the cases he witnesses; but concurrently with this, to take every occasion of acquiring skill in the practice of surgery. The dead-house and the wards are the two best schools of surgery. In the out-patient room many cases will be seen which do not find admission to the wards of most hospitals, but this practice will be of more value after than before a course of scientific surgical study. The operating theatre has attractions of its own more than sufficient, and we must caution students against the too common waste of time caused by witnessing operations, the need for and the mode of performing which they are entirely ignorant of, and when also they are unable to watch the subsequent progress of the case. Of the books that a student should read we would place BILLROTH'S *Surgical Pathology and Therapeutics* first and foremost, as forming the best groundwork on which to build. ERICHSEN'S, BRYANT'S, and HOLMES'S works on surgery have their individual merits, which are sufficiently apprised by the order in which we have placed them. Mr. HEATH'S book on *Minor Surgery* is an excellent manual, and Mr. BERKELEY HILL'S *brochure* on *Bandaging &c.* contains the best account of the way to apply bandages and splints. HOLDEN'S *Surgical Landmarks* will complete the library of most students. Those who desire to supplement these works will most profitably consult some of the articles in HOLMES'S *System of Surgery*, PAGET'S *Surgical Pathology* and his *Clinical Lectures and Essays*, Sir HENRY THOMPSON'S treatises on *Diseases of the Urinary Organs*, BERKELEY HILL or BUMSTEAD and TAYLOR on *Syphilis*, HAMILTON on *Fractures and Dislocations*, HOLMES on the *Surgical Diseases of Children* and WATSON CHEYNE on *Antiseptic Surgery*, HEATH, BELL or T. SMITH on *Operative Surgery*.

## PATHOLOGY AND MORBID ANATOMY.

The study of pathology is so linked with that of medicine and surgery that it can hardly be considered apart from them. But as at every school it takes, and rightly, a separate place in the curriculum, and as it is a subject of growing importance, some few words may be given to it here. The post-mortem room is the place where the facts of pathological anatomy are to be studied, and no opportunity should be lost by the student to be present at the examinations and demonstrations there given. If he be engaged in case-reporting or as clinical clerk he should make a point of seeing those cases which prove fatal investigated after death. Clinical observation of many diseases is of most value when amplified by post-mortem observation. The student should then familiarise himself with the characters of diseased organs, and if he be really in earnest in his work he should preserve specimens for future microscopical examination at his leisure. The course of pathological lectures is attended generally in the third winter or summer session, and in addition to formal lectures, there are generally facilities afforded for laboratory work, or practical classes are formed where the subject of pathological histology is worked at. The student will be well advised to pursue this subject practically. A third means of pathological study is that afforded by the museums. A well-ordered museum is a storehouse of information, the study of which should be utilised to the full. There are several books now specially devoted to students on this subject. Dr. GREEN'S little work is the first favourite, and besides Mrs. HART'S translation of CORNIL and RANVIER'S *Pathological Histology*, or the American translation of the same work, we are promised a translation of an admirable German text-book by ZIEGLER, and the publication of a text-book by Dr. COATS of Glasgow. These works may tend to supersede the well-known text-book of JONES and SIEVEKING, which was brought up to date a few years back under the editorship of Dr. PAYNE. The even better known book of Drs. WILKS and MOXON is admirably suited for study in connexion with the work of the post-mortem room; and in the methods of performing post-mortem examinations we have VIRCHOW'S guide and Mr. NEWTH'S. Upon surgical pathology there is Sir JAS. PAGET'S work and that by BILLROTH.

## MEDICAL JURISPRUDENCE.

The study of forensic medicine, or medical jurisprudence, should on no account be neglected. It is a branch of medical practice from which there is no escape. In cases of sudden accident or poisoning, the nearest medical man is bound by common humanity to give his services. He cannot shield himself under the plea that he is practising some special branch of his profession, and that the case in question is not one with which he is accustomed habitually to deal. As a legally qualified practitioner, he is bound to bring to bear what knowledge he possesses for the relief of the patient. A man's actions under these circumstances are liable to be made public; they may be stated in evidence in a court of law, and may be adversely criticised by counsel. It is evident, therefore, that by a want of knowledge of the principles of medical jurisprudence a medical man may bring (as many have done) great discredit upon himself. On the other hand, if in cases of emergency the practitioner

has acted with promptitude and discretion, his reputation may be established or improved. These considerations should stimulate even the laziest student to acquire a knowledge of this branch of medicine—a branch which more than any other is open to the criticism of the public press. It has been suggested by some that the courses of lectures on medical jurisprudence should be abolished, and that the points of contact between law and medicine should be dealt with by the teachers of surgery, medicine, obstetrics, and therapeutics. This is very well in theory, but since it is a fact that some questions have to be almost always omitted from all courses of lectures, it is certain that the legal relations of this or that branch of medicine would be the first thing to be sacrificed to the exigencies of time, and that without special lectures the student would fail to get adequate and systematic instruction in this most important branch of his education. The study of medical jurisprudence is full of interest, and we should strongly advise students not to content themselves with merely reading the smaller text-books. The large works, such as those of TAYLOR and BECK, are full of leading cases, many of which prove the correctness of the old adage that "truth is stranger than fiction." They rivet the attention, give a living interest to the facts of abstract science, and fix in the memory details which certainly tend to escape when acquired by the cramming process of reading and re-reading the uninteresting statements which are catalogued in the pages of those "Vade-mecums" which students love to carry in their pockets. The student who reads TAYLOR or BECK, as well as GUY, will acquire the valuable mass of facts given in the latter work with far greater ease than if he be content with the smaller book only. The study of toxicology is one of great scientific interest for this reason, that in cases of poisoning we have to deal with a disease brought about by a single cause, the nature of which is certain. The range and wonderful diversity of symptoms in different cases of poisoning by the same agent are facts which every student will do well to ponder over and take to heart, and the doing so cannot fail to lead him to appreciate the complexity of ordinary diseases, which are brought about usually by a plurality of causes, concerning the exact nature of which our knowledge is, with few exceptions, more or less indefinite and inexact. There is no lack of books on this branch of medicine. The large works of TAYLOR, BECK, and WOODMAN and TIDY are all reliable and full of information. The classical work of CASPER, translated by the New Sydenham Society, is full of interest, though somewhat behind in certain departments, and written from the point of view of German law and German customs. OGSTON, of Aberdeen, has written a good book of medium size, though incomplete. The well-known text-book of GUY and FERRIER is perhaps the best on the subject in the English language, its only fault being the somewhat condensed form in which the facts are given.

## THE GENERAL PRACTITIONER.

There is one fact that the student should always bear in mind—that the great bulk of his duty in after-life will have reference to cases and conditions that cannot be considered heroic or sensational, but which are the chief care of general practice, as they constitute the bulk of human trouble. In regard to this great point we should say these two things:

First, no case of disease, or feature of disease, should be despised for its commonness; and, secondly, that the more specific and definite the knowledge that can be gathered by a student on the common cases and facts of disease, the better practitioner will he turn out in the end. Nine students out of ten are destined not to be specialists. General practice is to be their field of labour, and there is no better field for usefulness, and even for distinction. No man is more valued in a community than the man who is helpful, and wise, and kind in all the emergencies of disease, from a toothache to a puerperal pyrexia. But though most students are to be general practitioners, their ultimate efficiency and success will depend very much on the amount of special knowledge which they can bring into general practice. Where one practitioner must be always sending his patients off to a specialist, another will be special enough in his knowledge to save his own credit and his patients' time and money. In order that the student may thus develop the greatest efficiency and credit as a practitioner, he must, after gaining a substantial knowledge of anatomy and physiology—without which all practice is a sort of quackery,—take the best opportunities of seeing common disease, and bring to its study unremitting attention. A cough, a rigor, a urinary deposit, a temperature in slight excess of the normal, a rash on the skin, the peevishness of a teething child, and remedies which a good practitioner uses in such cases, must have as much interest for him as a strangulated hernia, a glaucoma, or a case of myxœdema. Happy the student who accepts gratefully and yet with independent and even critical intelligence the best teaching of the best practitioners, whether general or special. Medical practice to him will be a joy rather than a care, and if he be occasionally in trouble, like other men, it will not be that greatest of all troubles—conscious incapacity for common duties born of inattention to common cases and common, though passing, opportunities of education. His destination may be to practise in a remote hamlet or the distant colony of an extended empire. On an emergency he may find himself confronted in such a solitude, and at midnight, with a case of ineffectual labour, or the still more trying one of retention of urine, and in the happy and timely use of his forceps or his catheter, in the relief of an agonised patient, and in his own consciousness of serviceableness, he will have reward enough, to say nothing of the greater rewards which accrue to faithful and religious men.

#### PUBLIC HEALTH AND MEDICAL OFFICER OF HEALTH.

Of late years the subject of Public Health has acquired steadily increasing attention in connexion with medical education. The appointment of a medical officer of health in every sanitary district, whether urban, rural, or port, has led many members of the profession to devote themselves exclusively to this branch of medical study and practice; and with a view of providing them with a diploma indicative of their special attainments, one or more of the Universities in each division of the kingdom have established a special examination. And quite apart from this, it is now, more than ever, felt that every medical practitioner should be acquainted with the principles of preventive medicine, and that when he is called in to advise as to the cure of disease,

he should also be able to indicate its cause, and to point out how any recurrence of it may in the future be prevented; this being especially the case in respect of infectious diseases. Indeed, the need for this has become definitely recognised both by several examining bodies and by many of the teachers in our medical schools. In several of the examinations for ordinary medical degrees or diplomas, questions bearing on public health are now invariably included, and some are so conducted as to give special prominence to this subject. Thus, candidates for the M.B. at the London University, and still more at the University of Oxford, are required to show that they have a general knowledge of the principles of public health and the prevention of disease. Indeed at the latter university the candidates are further required to give evidence of practical experience in sanitary investigations and in the detection of local conditions of sewerage, water-supply, dwelling accommodation, &c., which are calculated injuriously to affect the health of the population. To meet the requirement thus created special lectureships on Public Health have been established in several of our medical schools; and although attendance at the lectures is, as a rule, optional, yet many of the senior students recognise by their presence the advantage of acquiring information on this subject quite irrespective of any intention to devote themselves exclusively to this branch of the public service. The literature of public health is, like its study, of somewhat recent origin. The masterly reports issued by Mr. SIMON, C.B., F.R.S., in his capacity of medical officer to the Privy Council, and, later on, to the Local Government Board, should be studied by all who are interested in the subject, as should also the more recent reports by his successors in that office. Dr. FARR's articles on statistical questions in the reports of the Registrar-General and elsewhere contain much valuable and indispensable information; and as general text-books Dr. WILSON'S Handbook of Hygiene and Dr. PARKES' Manual of Practical Hygiene may, taken together, be perhaps regarded as the most useful. A fairly complete list of the various engineering, chemical, legal, microscopical, official, and other works bearing upon public health questions is published by the Cambridge University Press, together with papers for the examination in sanitary science in connexion with that university.

Notwithstanding the length of this Address, it has not been possible to consider all the subjects embraced in the medical student's education. Notices of the various Specialities have reluctantly been omitted. We must, however, warn the student against giving himself up to the attractions of Specialism in study or in practice before he is well grounded in the general principles of Medicine, Surgery, and Pathology. On the other hand, the more important diseases of the eye, ear, skin, throat, and of the nervous system should receive a fair amount of attention from every senior student. With these, as with general diseases, there must be direct observation and personal contact with actual patients. Plenty of opportunities are now afforded at all the principal medical schools for the study and investigation of special diseases.

## SESSION 1882-83.

GENERAL COUNCIL OF MEDICAL EDUCATION  
AND REGISTRATION OF THE UNITED  
KINGDOM.

**Registration of Medical Students.**—The following regulations have been adopted by the General Medical Council in reference to the registration of students in medicine:—Every medical student shall be registered in the manner prescribed by the General Medical Council. No medical student shall be registered until he has passed a preliminary examination as required by the General Medical Council,<sup>1</sup> and has produced evidence that he has commenced medical study. The commencement of the course of professional study recognised by any of the qualifying bodies shall not be reckoned as dating earlier than fifteen days before the date of registration. The registration of medical students shall be placed under the charge of the branch registrars. Each of the branch registrars shall keep a register of medical students according to a prescribed form, wherein is set forth the name, the preliminary examination and date thereof, the date of registration, and the place and date of commencement of medical study, as certified by a master or a teacher, or an official in a medical school or hospital. Every person desirous of being registered as a medical student shall apply to the branch registrar of the division of the United Kingdom in which he is residing; and shall produce or forward to the branch registrar a certificate of his having passed a preliminary examination as required by the General Medical Council, and evidence that he has commenced medical study. The branch registrar shall enter the applicant's name and other particulars in the Students' Register, and shall give him a certificate of such registration. Each of the branch registrars shall supply to the several qualifying bodies, medical schools, and hospitals, in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of medical students. The several Branch Councils—and in England the Executive Committee, if its meeting be more convenient and the case be urgent—have power to admit special exceptions to the foregoing regulations as to registration, for reasons which shall appear to them satisfactory. A copy of the Register of Medical Students, prepared by each of the branch registrars, shall be transmitted on or before Dec. 31st, in each year, to the registrar of the General Council, who shall, as soon as possible thereafter, prepare and print, under the direction of the Executive Committee, an alphabetical list of all students registered in the preceding year, and supply copies of such authorised list to each of the bodies enumerated in Schedule A to the Medical Acts, and through the branch registrars to the several medical schools and hospitals. The several qualifying bodies are recommended not to admit to the final examination for a qualification under the Medical Acts any candidate (not exempted from registration) whose name has not been entered in the Medical Students' Register at least forty-five months previously.<sup>2</sup> In the case of candidates from other than schools of the United Kingdom, the Branch Councils—and in England the Executive Committee, if its meeting be more convenient and the case be urgent—have power to admit exceptions to this recommendation.

Pursuant to resolutions passed by the General Medical Council at its session in July, 1880, the Regulations for Preliminary General Education, which took effect from Jan. 1st, 1882, are as follows:—

No person shall be allowed to be registered as a medical student unless he shall have previously passed a Preliminary Examination in the subjects of General Education as specified

<sup>1</sup> Exception may be made in the case of a Student from any Indian, Colonial, or Foreign University or College, who shall have passed the Matriculation or other equivalent Examination of his University or College, provided such Examination fairly represents a standard of General Education equivalent to that required in this country.

<sup>2</sup> Exception may be allowed in the case of any Graduate in Medicine of an Indian, or Colonial, or Foreign University, or of any Student who, having completed the full time required by the Medical Council, and having given satisfactory evidence of General Education, shall have spent the whole or three-fourths of that period at an Indian, Colonial, or Foreign University, the several Licensing Bodies being requested to communicate to the Council annually, in the month of January, a statement of the action taken by them respectively during the last preceding calendar year, in regard of such exceptional cases.

in the following list:—1. English Language, including Grammar and Composition.<sup>3</sup> 2. English History. 3. Modern Geography. 4. Latin, including Translation from the original and Grammar. 5. Elements of Mathematics, comprising (a) Arithmetic, including Vulgar and Decimal Fractions; (b) Algebra, including Simple Equations; (c) Geometry, including the first two books of Euclid or the subjects thereof. 6. Elementary Mechanics of Solids and Fluids, comprising the Elements of Statics, Dynamics, and Hydrostatics.<sup>4</sup> 7. One of the following optional subjects: (a) Greek; (b) French; (c) German; (d) Italian; (e) any other Modern Language; (f) Logic; (g) Botany; (h) Elementary Chemistry.

Communications relating to the Medical Students' Register, or to the registration of medical students, should be sent to the registrars to the following addresses:—

W. J. C. Miller, B.A., Registrar of the General Council and of the Branch Council for England, 299, Oxford-street, London, W. — Archibald Inglis, M.D., Registrar of the Branch Council for Scotland, 33, Albany-street, Edinburgh. — W. E. Steele, M.D., Registrar of the Branch Council for Ireland, 35, Dawson-street, Dublin.

REGULATIONS  
OF THEMEDICAL EXAMINING BOARDS IN THE  
UNITED KINGDOM.

## UNIVERSITY OF OXFORD.

Every student must reside in one or other of the Colleges or Halls, or in licensed lodgings, for three years, passing at least two examinations in Arts, and one in either Mathematics, Natural Science, Law, Modern History, or Theology, when, if he obtain a first, second, or third class, he can take his B.A. degree; if he do not gain such honour, he has to pass a third examination in *Literis Humanioribus*.

A student desiring to graduate in Medicine must pass the requisite examinations for the degree of B.A. He must afterwards spend two years in study<sup>5</sup> prior to the first or scientific examination for the degree of Bachelor of Medicine, and two years more, after passing the first, prior to the final or practical examination for the same degree. Evidence must be brought to show that he has studied the practical parts of his profession in a first-class hospital.

There is an examination in State Medicine and Public Health, to which Bachelors of Medicine of the University are admissible. Copies of the examination-papers in the several examinations may be obtained through any bookseller.

A dissertation has to be publicly read, three years after obtaining the M.B., before being eligible for the M.D.

The study of Natural Science is carried on at the Museum, in which are extensive opportunities for the study of Physics, Chemistry, General, Comparative, and Human Anatomy, Histology, and other departments of Natural Science, together with courses of lectures and of practical instruction by the several professors. Collections illustrate the various subjects. There is in the medical department a pathological series, including the collection of Schroeder Van der Kolk, and a sanitary laboratory. The Radcliffe Library, containing above 40,000 scientific volumes, is open to all students daily from 10 till 4, and on certain evenings during term. There are lectures and practical instruction in

<sup>3</sup> The Examinations in General Education conducted by Universities will be accepted as heretofore, but if in any of these Examinations the subjects of Elementary Mechanics of Solids and Fluids are not included, a knowledge of these subjects will be required at a subsequent Examination.

<sup>4</sup> The General Medical Council will not consider any Examination in the English Language sufficient that does not fully test the ability of the candidate:—(1) To write sentences in correct English on a given theme, attention being paid to spelling and punctuation as well as to composition; (2) to write correctly from dictation; (3) to explain the grammatical construction of sentences; (4) to point out the grammatical errors in sentences ungrammatically composed, and to explain their nature; and (5) to give the derivation and definition of English words in common use.

<sup>5</sup> This subject may be passed either as Preliminary, or before, or at the first Professional Examination.

<sup>6</sup> If he have taken the higher honours in the Natural Science School he may go in for the first M.B. examination on the first opportunity, and so have a longer period of practical study before the second M.B. examination. By a recent decree the "testatur" of the Natural Science School exempts from examination in Physics and Chemistry at the first M.B. This examination therefore comprises in the cases of such candidates Anatomy and Physiology alone.

Botany at the Botanical Gardens, and clinical instruction at the Infirmary.

The medical examinations take place every year in the Trinity (summer) term. Scholarships of about the value of £75 are obtainable at Christ Church, Magdalen, and other colleges, by competitive examination in Natural Science. Every year a Radcliffe Travelling Fellowship is competed for by any who, having taken a first class in any of the schools, or having obtained a University prize or scholarship, propose to study Medicine. The Travelling Fellows receive £200 a year for three years, half this period being spent in study abroad.

More detailed information may be obtained from the University Calendar; from the Student's Handbook to the University; from the Regius Professor of Medicine; from the Professors in the several departments; from E. Chapman, Esq., M.A., Frewin Hall; and from the Sub-Librarian in the Radcliffe Library at the Museum.

#### UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep terms for three years by residence in the University. He must pass the Previous Examination in Classics and Mathematics, which may be done, and should if possible be done, in the first or second term of residence, or, which is best, through the Oxford and Cambridge Schools Examination Board or the Local Examinations, before commencing residence. He may then devote himself to medical study in the University, attending the hospital and the medical lectures, dissecting, &c. Or he may proceed to take a degree in Arts, either continuing mathematical and classical study, and passing the ordinary examinations for B.A., or going out in one of the Honour Triposes. The Natural Science Tripos is preferred by most medical students, some of the subjects for this Tripos examination (Chemistry, Botany, Human and Comparative Anatomy, and Physiology) forming part of the series of medical study.

The expenses of residence, lectures, &c., at a College are about £150 per annum; but these are in many cases lessened by Scholarships, ranging in value from £20 to £80 a year, which are very numerous, and obtainable by most students of industry and ability. They are chiefly given for mathematical and classical proficiency. Some may be obtained at once, even before entering; and notices of the examinations for these are given from time to time under the head of "University Intelligence" in *The Times* and other newspapers. Scholarships are given for Natural Science in Trinity, St. John's, St. Peter's, Clare, Christ's, Sydney, Pembroke, Caius, and Downing Colleges; the examinations begin at Easter, also in June and October.<sup>7</sup>

Non-Collegiate students can reside at less expense (£80 or £90 a year) than those who enter a College. They are allowed to attend certain of the College lectures and all the professors' lectures, and have the same University status and privileges as the other students. They are under the superintendence of the Rev. F. Howard, Non-Collegiate Student's Office, Trumpington-street, Cambridge, from whom further information may be obtained. Cavendish College has been recently founded, to afford special facilities for obtaining a degree at a moderate cost, and at the earliest practicable age. Information may be obtained from J. Cox, Esq., Warden of the College.

For the degree of *Bachelor of Medicine* five years of medical study are required, except in the case of medical students who have graduated with honours as Bachelors of Arts, four years being then sufficient. This time may be spent in Cambridge or elsewhere. The earlier portion of it is usually spent in Cambridge, the student remaining in the University till he has passed the examination for the Natural Sciences Tripos and the first and second examinations for M.B.

There are three examinations for M.B. The *first* in Chemistry and other branches of Physics and Botany. The *second* in Anatomy and Physiology (Human and Comparative), and Pharmacology. The *third*, which may be taken in two parts (at the conclusion of Medical study), in Medicine, Surgery, Midwifery, and Medical Jurisprudence. The examinations are partly in writing and partly oral, in

the hospital, in the dissecting-room, and in the laboratories. They take place twice annually (in June and December).

An Act has to be kept, which consists in reading an original thesis and passing a *viva voce* examination on the subject of the thesis and on other subjects.

Previously to the first examination, lectures must have been attended on Chemistry (with manipulations) and Botany. Previously to the second examination, the student must have attended lectures on Human Anatomy and Physiology, Comparative Anatomy, Materia Medica and Pharmacy, and Pathology; have Dissected for one season and attended Hospital Practice one year. Previously to the third examination, lectures must have been attended on Pathological Anatomy, the Principles and Practice of Physic, Clinical Medicine, Clinical Surgery, Midwifery (with ten cases), and Medical Jurisprudence; also Hospital Practice for three years. The candidate must also have been a clinical clerk, or have had special charge of patients in a hospital, dispensary, or parochial union for six months.

The degree of *Doctor in Medicine* may be taken three years after M.B. An Act has to be kept, with *viva voce* examination; and an extempore essay has to be written on some subject relating to Physiology, Pathology, the Practice of Medicine, or State Medicine. A Master of Arts proceeding to M.D. is required to produce the same certificates and pass the same examinations as for M.B.

The candidate for the degree of *Bachelor of Surgery* is required to have passed the *first* and *second* examinations, and the first, or surgical part, of the *third* examination for M.B.; to have attended the Surgical practice of a hospital for two years, have acted as House Surgeon or Dresser for six months, and have gone through a course of instruction in Practical Surgery. The subjects of the Examination are Surgical Operations and the Application of Surgical Apparatus, and the Examination of Surgical patients.

For the degree of *Master in Surgery* the candidate must have passed the three examinations for M.B., and have attended lectures on Human Anatomy (a second course), on the Principles and Practice of Surgery, Clinical Surgery; he must have dissected a second season, have attended the Surgical Practice at a recognised hospital for three years, and have held a house-surgeoncy or dressership for six months. He is then required to pass an examination in Surgical Anatomy, Pathology, and the Principles and Practice of Surgery, and Clinical Surgery.

The next examination in Sanitary Science by the University of Cambridge will take place early in October. Candidates (whose names must be on the Medical Register of the United Kingdom) should send their names to Professor Liveing, Cambridge, before Sept. 25th.

The following is a summary of the course which a student (commencing at the University, say, in October, 1882) may follow:—He enters at any one of the colleges, or as a non-collegiate student, and passes the Previous Examination (in Classics and Mathematics), in October, 1882, or in April, 1883, unless he has already passed the equivalent examination under the Local Examinations or the Oxford and Cambridge Schools Examination Board. He is then registered as a student of medicine. Medical study in the University for two years. Natural Sciences Tripos Examination (in Human and Comparative Anatomy, Chemistry, and Botany), in June, 1885; this admits to the B.A. degree in June, 1885. Second Examination for M.B. (in Human Anatomy and Physiology, and Materia Medica), June or December, 1885, or May, 1886. Third examination for M.B. (in Medicine, Surgery, Midwifery, and Medical Jurisprudence), November, 1887; Examination for B.C. (in Surgical Anatomy, Pathology, and Surgery), November, 1887. Degree of M.B. or B.C., Nov., 1887. Part of the period of medical study is thus spent in Cambridge, and part (say after the second examination) in London or elsewhere.

Attendance at the hospital and on the lectures on Anatomy, Chemistry, &c., is recognised by the Universities of Cambridge and London, and by the College of Surgeons.

The students should remain in Cambridge during part of the long vacation (July and August) and part of the Christmas vacation, as well as during the terms.

#### UNIVERSITY OF LONDON.

The *Matriculation Examinations* take place on the second Monday in January and the third Monday in June. Candidates must be above sixteen years of age. The fee for the examination is £2. Provincial examinations are appointed

<sup>7</sup> For an account of these Scholarships see THE LANCET of April 12th, 1882; and for an account of the Scholarships for Natural Sciences see *Nature* in the early part of each year. Further information may be obtained from the *Student's Handbook to the University*, published by Messrs. Deighton, Cambridge, price 1s. 6d., and the *Student's Guide to the University*.

by the Senate from time to time at specified centres. Several scholarships, exhibitions, and prizes are associated with these examinations.

The *Preliminary Scientific (M.B.) Examination* takes place once in each year, and commences on the third Monday in July.<sup>8</sup> No candidate will be admitted to this examination until he shall have either passed the Matriculation Examination or taken a degree in Arts in one of the Universities of Sydney, Melbourne, Calcutta, or Madras (provided that Latin was one of the subjects in which he passed); nor unless he have given notice of his intention to the registrar at least fourteen days before the commencement of the examination. Fee for this examination £5.

Candidates are examined on the following subjects: Inorganic Chemistry, Experimental Physics, Botany and Vegetable Physiology, and Zoology.

Any candidate who has passed the Preliminary Scientific (M.B.) Examination may be examined at the Honours Examination next following the Preliminary Scientific Examination at which he has passed for honours in (1) Experimental Physics, (2) Chemistry, (3) Botany, (4) Zoology, unless he have previously obtained an exhibition in any one of these subjects at the Intermediate Examination in Science, in which case he shall not be admissible to the examination for honours in that subject.

*Bachelor of Medicine.*—Every candidate for the degree of Bachelor of Medicine will be required—1. To have passed the Matriculation Examination in this University (unless he have taken a degree in Arts in one of the Universities of Sydney, Melbourne, Calcutta, or Madras, and Latin was one of the subjects in which he passed). 2. To have passed the Preliminary Scientific Examination. 3. To have been engaged in his professional studies during four years subsequently to matriculation or graduation in Arts at one or more of the medical institutions or schools recognised by this University, one year at least of the four to have been spent in one or more of the recognised institutions or schools in the United Kingdom. 4. To pass two examinations in Medicine.

*Intermediate Examination.*—The Intermediate Examination in Medicine takes place once in each year, and commences on the last Monday in July. No candidate shall be admitted to this examination unless he have passed the Preliminary Scientific Examination at least one year previously, and have produced certificates to the following effect:—1. Of having completed his nineteenth year. 2. Of having, subsequently to having passed the Matriculation Examination, or taken a degree in Arts in one of the before-named universities, been a student during two years at one or more of the medical institutions or schools recognised by this University, and of having attended a course of lectures on each of three of the subjects in the following list:—Descriptive and Surgical Anatomy, Histology and Physiology, Pathological Anatomy, Materia Medica and Pharmacy, General Pathology, General Therapeutics, Forensic Medicine, Hygiene, Obstetric Medicine and Diseases peculiar to Women and Infants, Surgery, Medicine. 3. Of having, subsequently to having passed the Matriculation Examination, or taken a degree in Arts, Dissected during two winter sessions. 4. Of having, subsequently to having passed the Matriculation Examination or taken a degree in Arts, attended a course of Practical Chemistry, comprehending practical exercises in conducting the more important processes of General and Pharmaceutical Chemistry; in applying tests for discovering the adulteration of articles of the Materia Medica, and the presence and nature of poisons; and in the examination of mineral waters, animal secretions, urinary deposits, calculi, &c. 5. Of having attended to Practical Pharmacy, and of having acquired a practical knowledge of the preparation of medicines. These certificates (as is the case also with all the certificates hereinafter mentioned) must be transmitted to the registrar at least fourteen days before the commencement of examination. Fee for this examination, £5.

Candidates will be examined in the following subjects:—Anatomy, Physiology, and Histology, Materia Medica and Pharmaceutical Chemistry, Organic Chemistry. Candidates will not be approved by the examiners unless they have shown a competent knowledge in all these subjects.

Any candidate who has passed the Intermediate Examination

in Medicine in all its subjects at one time may be examined at the Honours Examination next following the Intermediate Examination in Medicine, at which he passed for Honours in (1) Anatomy, (2) Materia Medica and Pharmaceutical Chemistry, (3) Physiology and Histology, and (4) Organic Chemistry. The examinations take place in the week following that in which the Pass Examination commenced. They are conducted by means of printed papers and practical work.

If, in the opinion of the examiners, sufficient merit be evinced, the candidate who shall distinguish himself the most in Anatomy, and the candidate who shall distinguish himself the most in Histology and Physiology, will each receive an exhibition of £40 per annum for the next two years; the candidate who shall distinguish himself the most in Organic Chemistry, and the candidate who shall distinguish himself the most in Materia Medica and Pharmaceutical Chemistry, will each receive an exhibition of £30 per annum for the next two years. On receiving each quarterly instalment he must declare his intention of presenting himself at the M.B. Examination within three academical years from the time of his passing the Intermediate Examination in Medicine. Under the same circumstances, the first and second candidates in Anatomy and in Histology and Physiology, and the first candidate in Organic Chemistry and in Materia Medica and Pharmaceutical Chemistry, will each receive a gold medal of the value of £5.

*M.B. Examination.*<sup>9</sup>—The M.B. Examination takes place once in each year, and commences on the first Monday in November. Each candidate, two academical years after passing the First Examination, must produce certificates to the following effect:—1. Of having passed the Intermediate Examination. 2. Of having, subsequently to having passed the Intermediate Examination, attended a course of lectures on each of two of the subjects enumerated in Section 2 of the regulations for that examination, and for which the candidate had not on that occasion presented certificates. 3. Of having conducted at least twenty labours. Certificates on this subject will be received from any legally qualified practitioner in Medicine. 4. Of having attended the Surgical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Surgery. 5. Of having attended the Medical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Medicine. 6. Of having, after having attended Surgical and Medical Hospital Practice for at least twelve months subsequently to passing the Intermediate Examination, attended to Practical Medicine, Surgery, or Obstetric Medicine, with special charge of patients, in a hospital, infirmary, dispensary, or parochial union, during six months, such attendance not to be counted as part of either the Surgical or the Medical Hospital Practice prescribed in clauses 4 and 5. 7. Of having acquired proficiency in Vaccination. Certificates on this subject will be received only from the authorised vaccinators appointed by the Privy Council. The candidate must also produce a certificate of moral character from a teacher in the last school or institution at which he has studied, as far as the teacher's opportunity of knowledge has extended. The fee for this examination is £5.

Candidates will be examined in the following subjects:—General Pathology, General Therapeutics and Hygiene, Surgery, Medicine, Obstetric Medicine, Forensic Medicine. The examinations will include questions in Surgical and Medical Anatomy, Pathological Anatomy, and Pathological Chemistry. Candidates will not be approved by the examiners unless they have shown a competent knowledge in all the subjects of examination.

Any candidate who has passed the M.B. Examination may be examined at the Honours Examination next following the M.B. Examination at which he has passed, for Honours in (1) Medicine, (2) Obstetric Medicine, and (3) Forensic Medicine. The examinations commence in the week following that in which the Pass Examination terminated. Except in the case of Forensic Medicine they are conducted by means of printed papers, but the examiners will not be precluded from putting *visd voce* questions upon the written answers of the candidates.

If, in the opinion of the examiners, sufficient merit be

<sup>8</sup> Candidates for the Degree of M.B. are strongly recommended by the Senate to pass the Preliminary Scientific Examination before commencing their regular medical studies, and to devote a preliminary year to preparation for it according to the following programme:—Winter Session: Experimental Physics, Chemistry (especially Inorganic), Zoology. Summer Session: Practical Chemistry (Inorganic), Botany.

<sup>9</sup> Any candidate for the M.B. Examination who has passed the Intermediate Examination under the former regulations, will be required to have also passed the examination in Physiology at some previous Intermediate Examination carried on under the present regulations, at which examination he shall not be allowed to compete for Honours.

evinced, the candidate who shall distinguish himself the most in Medicine will receive £50 per annum for the next two years, with the style of University Scholar in Medicine. Under the same circumstances the candidate who shall distinguish himself the most in Obstetric Medicine will receive £30 per annum for the next two years, with the style of University Scholar in Obstetric Medicine. Under the same circumstances the candidate who shall distinguish himself the most in Forensic Medicine will receive £30 per annum for the next two years, with the style of University Scholar in Forensic Medicine. Under the same circumstances the first and second candidates in each of the preceding subjects will each receive a gold medal of the value of £5.

**Bachelor of Surgery.**—The examination for the degree of Bachelor of Surgery takes place once in each year, and commences on the Tuesday following the fourth Monday in November. Candidates must produce certificates to the following effect:—1. Of having passed the Second Examination for the degree of Bachelor of Medicine in this University. 2. Of having attended a course of instruction in Operative Surgery, and of having operated on the dead subject. Fee for this examination, £5.

Any candidate who has passed the B.S. Examination may be examined at the Honours Examination next following the B.S. Examination at which he has passed, for Honours in Surgery. The examination takes place on Tuesday in the week following the Pas Examination, and is conducted by means of printed papers. If in the opinion of the examiners sufficient merit be evinced, the candidate who shall distinguish himself the most will receive £50 per annum for the next two years, with the style of University Scholar in Surgery. Under the same circumstances, the first and second candidates will each receive a gold medal of the value of £5.

**Master in Surgery.**—The examination for the degree of Master in Surgery takes place once in each year, and commences on the fourth Monday in November.

Candidates must produce certificates to the following effect:—1. Of having taken the degree of Bachelor of Surgery in this University.<sup>10</sup> 2. Of having attended, subsequently to having taken the degree of Bachelor of Surgery in this University: (a) To Clinical or Practical Surgery during two years in a hospital or medical institution recognised by this University. (b) Or to Clinical or Practical Surgery during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession. (c) Or of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Surgery in this University. One year of attendance on Clinical or Practical Surgery, or two years of practice, will be dispensed with in the case of those candidates who at the B.S. Examination have been placed in the first division. 3. Of moral character, signed by two persons of respectability. Fee for this degree, £5. The examination is conducted by means of printed papers and *visà voce* interrogation.

Candidates will be examined in Logic and Psychology, and Surgery, and will not be approved unless they have shown a competent knowledge in both the subjects of examination.

If sufficient merit be evinced, the candidate who shall distinguish himself the most in Surgery at this examination will receive a gold medal of the value of £20.

**Doctor of Medicine.**—The examination for this degree takes place once in each year, and commences on the fourth Monday in November.

Candidates must produce certificates to the following effect:—1. Of having passed the Examination for the degree of Bachelor of Medicine in this University. 2. Of having attended, subsequently to having taken the degree of Bachelor of Medicine in this University, (a) to Clinical or Practical Medicine during two years in a hospital or medical institution recognised by this University; or (b) to Clinical or Practical Medicine during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice

of his profession. (c) Or of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Medicine in this University. One year of attendance on Clinical or Practical Medicine or two years of practice will be dispensed with in the case of those candidates who at the M.B. Examination have been placed in the first division. 3. Of moral character, signed by two persons of respectability. Fee for this degree, £5. The examination is conducted by means of printed papers and *visà voce* interrogation.

Candidates will be examined in Logic and Psychology, and Medicine, and will not be approved unless they have shown a competent knowledge in both the subjects of examination. If sufficient merit be evinced, the candidate who shall distinguish himself the most in medicine at the examination for the M.D. degree will receive a gold medal of the value of £20.

**Public Health.**—A Special Examination will be held once in every year in subjects relating to Public Health, to commence on the second Monday in December. Candidates must have passed the Second Examination for the B.M. degree in this University at least one year previously; and must give notice of their intention to the Registrar, at least *two calendar months* before the commencement of the examination. The fee for this examination is £5. Candidates will be examined in Chemistry, and Microscopy, Meteorology, Geology, Physics and Sanitary Apparatus, Vital Statistics, Hygiene, and Sanitary Law. The examination will be both written and practical, and will extend over four days. Candidates will not be approved unless they have shown a competent knowledge in all the principal subjects of the examination. If sufficient merit be evinced the candidate who shall distinguish himself the most shall receive a gold medal of the value of £5.

#### UNIVERSITY OF DURHAM.

A certificate, two licences, and three degrees are conferred—viz., a certificate of proficiency in Sanitary Science, a licence in Medicine and a licence in Surgery; and the degrees of Bachelor in Medicine, Master in Surgery, and Doctor in Medicine.

For the degree of *Bachelor in Medicine* there are two professional examinations; the first being held twice yearly—viz., in October (in 1882 commencing on the 9th) and April (in 1883 commencing on the 23rd); the second twice yearly—viz., in December (in 1882 commencing on the 4th) and in June (in 1883 commencing on the 18th).

The subjects for the first examination are—Anatomy, Physiology, Chemistry, and Botany. Candidates must produce the following certificates:—(1) Of registration as a medical student. (2) Of having passed one of the following examinations in Arts: (a) the examination for graduation in Arts at one of the following universities—Oxford, Cambridge, Durham, Dublin, London, Queen's (Ireland), Edinburgh, Glasgow, St. Andrews, Aberdeen, Calcutta, Madras, Bombay, McGill College (Montreal), and Queen's College (Kingston); or (b) the Preliminary or Extra-professional examination for graduation in medicine at one of the following universities—London, Edinburgh, Glasgow, St. Andrews, Aberdeen, and Queen's (Ireland); or (c) the Preliminary Examination in Arts qualifying for the membership of the Royal College of Physicians of London or for the fellowship of the Royal College of Surgeons of England; or (d) the Preliminary Examination in Arts for the degrees in medicine of the University of Durham (in 1883 commencing on April 7th and September 18th). Candidates who, at the commencement of their professional education, passed the Arts examination for registration only, may pass in the extra subjects required for the M.B. Durham either before or after presenting themselves for the first examination for the degree, but must do so before presenting themselves for the final examination. (3) Of attendance on two courses of Anatomy, on one of Physiology, on one of Theoretical and one of Practical Chemistry, and on one of Botany; of twelve months' dissection; and of attendance on a course of Practical Physiology of not less than thirty lessons.

The subjects for the Second Examination are Medicine, Surgery, and Public Health, Pathology, Materia Medica, Therapeutics, Midwifery, and Diseases of Women and Children, and Medical Jurisprudence. For it candidates must produce the following certificates—viz. (1), of being not less than twenty-one years of age; (2) of good moral cha-

<sup>10</sup> Candidates who have obtained the degree of Bachelor of Medicine previously to 1866 will be admitted to the examination for the degree of Master in Surgery without having taken the degree of Bachelor of Surgery; and in the case of such candidates the attendance on surgical practice required by Regulation 2 may commence from the date of the M.B. degree.

acter; and (3) of attendance on the remainder of the course of medical and surgical study as prescribed by the Royal College of Surgeons of England, together with the following additional subjects—viz., one course of lectures on Medicine, one on Therapeutics, one on Public Health, and one on Botany and on Medical Hospital Practice, with Clinical Lectures during one winter and one summer session. There must be proof that the whole course of professional study has occupied at least four years.

N.B.—It is required that one of the four years of professional education shall be spent in attendance at the College of Medicine, Newcastle-upon-Tyne. During the year so spent the candidates must attend at least two courses of lectures in the winter session and two in the summer session, together with the class and test examinations held in connexion with those classes, and must also attend hospital practice and clinical lectures at the infirmary during the same period. Candidates may fulfil this portion of the curriculum at any period before they present themselves for the Final Examination for the degree. The other three years of the curriculum may be spent either at Newcastle-upon-Tyne or at one or more of the schools recognised by the licensing bodies named in Schedule A of the Medical Act, 1858. Candidates who are already qualified by other of the licensing bodies are required to attend for one winter and one summer session at the College of Medicine, Newcastle-upon-Tyne.

For the Degree of *Master in Surgery* the candidate must have passed the Examination for the Degree of Bachelor in Medicine and must have attended one course of lectures on Operative Surgery. Each candidate will have an additional paper on Surgery, and will have to perform operations on the dead body, and to explain the use of instruments.

For the Degree of *Doctor of Medicine* candidates must be not less than twenty-four years of age, must have obtained the degree of M.B. at least two years previously, and in the interim have been engaged in medical or surgical practice. Each candidate will be required to write an essay on some medical subject selected by himself and approved by the Professor of Medicine, and to pass an examination thereon, and must be prepared to answer questions on the other subjects of his curriculum in so far as they are related to the subject of his essay.

Candidates for any of the above degrees must give at least twenty-eight days' notice to the Registrar of the College.

*The Degree of Doctor of Medicine, for Medical Practitioners of fifteen years' standing, without residence.*—There is a special Examination, under the following regulations:—

1. That the candidate shall be registered by the General Council of Medical Education and Registration of the United Kingdom.
2. That the candidate shall have been in the active practice of his profession for fifteen years as a qualified practitioner.
3. That the candidate shall not be under forty years of age.
4. That the candidate shall produce a certificate of moral character from three registered members of the medical profession.
5. That if the candidate shall not have passed, previous to his Professional Examination (in virtue of which he has been placed on the Register), an examination in Arts, he shall be required to pass an examination in Classics and Mathematics.
6. That if the candidate shall have passed, previous to his Professional Examination (in virtue of which he has been placed on the Register), a preliminary examination, he shall be required to translate into English passages of certain named Latin authors.
7. That the candidate shall pass an examination in the following subjects: *a*, Principles and Practice of Medicine, including Psychological Medicine, and Hygiene; *b*, Principles and Practice of Surgery; *c*, Midwifery and Diseases peculiar to Women and Children; *d*, Pathology, Medical and Surgical; *e*, Anatomy, Medical and Surgical; *f*, Medical Jurisprudence and Toxicology; *g*, Therapeutics.
8. That the fee shall be 50 guineas.
9. That if the candidate shall fail to satisfy the examiners, the sum of 20 guineas shall be retained; but that, if he shall again offer himself for the examination, the sum of 40 guineas only shall then be required.

Examinations in accordance with the above regulations will commence on Dec. 4th, 1882, and June 18th, 1883, in the College of Medicine, Newcastle-upon-Tyne. Gentlemen intending to offer themselves as candidates are requested to forward their names to Dr. Luke Armstrong, registrar of the University of Durham College of Medicine, Newcastle-upon-Tyne, on or before Nov. 1st, 1882, or May 1st, 1883,

together with the fee and the before-mentioned certificates.

*Certificate of Proficiency in Sanitary Science.*—Candidates for this certificate must be registered medical practitioners and have attended one course of lectures on Public Health, at the College of Medicine, Newcastle-upon-Tyne, extending over one winter session. The examination will be by written papers, practical and *visd voce*, and will commence on October 9th, 1882, and on April 23rd, 1883. In the practical examination the candidate will be required:—To report upon the condition of some actual locality, to analyse liquids and gases, to explain the construction and use of instruments employed in meteorology, and to make microscopic examinations. The fee is £5 5s.

Medical Officers of Health of five years' standing, who were registered as qualified members of the profession before January 1st, 1878, may obtain the certificate of proficiency in Sanitary Science under the following conditions:—They must be registered medical practitioners, and be not under thirty years of age; they will be required to pass the same examination as before mentioned, write an essay upon some practical sanitary subject, and will be examined upon the essay, and upon other sanitary questions. The fee is £10 10s. During the ensuing year two examinations will be held, commencing the one on October 9th, 1882, the other on April 23rd, 1883.

#### UNIVERSITY OF EDINBURGH.

The session 1882-83 will be opened on October 24th.

Three medical degrees are conferred by the University of Edinburgh—namely, Bachelor of Medicine (M.B.), Master in Surgery (C.M.), and Doctor of Medicine (M.D.). The degree of Master in Surgery is not conferred on any person who does not also at the same time obtain the degree of Bachelor of Medicine. All candidates for these degrees must give evidence of having obtained a satisfactory general education.

1. The preliminary branches of extra-professional education are English, Latin, Arithmetic, the Elements of Mathematics, and the Elements of Mechanics; and the proficiency of students in these branches is ascertained by examination prior to the commencement of their medical study.

2. No candidate is admitted to a professional examination who has not passed a satisfactory examination on at least two of the following subjects (in addition to the subjects mentioned above):—Greek, French, German, Higher Mathematics, Natural Philosophy, Logic, Moral Philosophy; and the examination on these latter subjects also takes place before the candidate has entered on his medical curriculum.

3. A degree in Arts (not being an honorary degree) in any one of the universities of England, Scotland, or Ireland, or in any foreign or colonial university specially recognised for this purpose by the University Court, exempts from all preliminary examination; and an examination in Arts by any corporate body, whose examination has been recognised as qualifying for entrance on medical study by resolution of the General Medical Council of the United Kingdom, provided the said examination by the said corporate body shall also be approved by the University Court, shall exempt *pro tanto* from preliminary examination in Arts, on the subjects comprised in the examination of the said corporate body.

4. No one is admitted to the degree of Bachelor of Medicine or Master in Surgery who has not been engaged in medical and surgical study for four years—the medical session of each year, or *annus medicus*, being constituted by at least two courses of not less than one hundred lectures each, or by one such course and two courses of not less than fifty lectures each; with the exception of the clinical courses, in which lectures are to be given at least twice a week during the prescribed periods.

5. Every candidate for the degrees of M.B. and C.M. must give sufficient evidence by certificates—(a) That he has studied each of the following departments of medical science—namely, Anatomy, Chemistry, Materia Medica, Institutes of Medicine or Physiology, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Children, and General Pathology, each during courses including not less than one hundred lectures; Practical Anatomy, a course of the same duration as those of not less than one hundred lectures; Practical Chemistry, three months; Practical Midwifery, three months at a midwifery hospital, or a certificate of attendance on six cases from a registered medical practitioner; Clinical Medicine, Clinical

Surgery,<sup>11</sup> courses of the same duration as those of not less than one hundred lectures, or two courses of three months' lectures, being given at least twice a week; Medical Jurisprudence, Botany, Natural History (including Zoology), during courses including not less than fifty lectures. (b) That he has attended, for at least two years, the medical and surgical practice of a general hospital which accommodates not fewer than eighty patients, and possesses a distinct staff of physicians and surgeons. (c) That he has attended during a course of not less than fifty hours' instruction the class of Practical Materia Medica in the University of Edinburgh, or a similar class conducted in a university or recognised school of medicine, or a similar class conducted by a teacher recognised by the University Court; or that he has been engaged, for at least three months, by apprenticeship or otherwise, in compounding and dispensing drugs at the laboratory of a hospital, dispensary, member of a surgical college or faculty, licentiate of the London or Dublin Society of Apothecaries, or member of the Pharmaceutical Society of Great Britain. (d) That he has attended, for at least six months, by apprenticeship or otherwise, the out-practice of a hospital, or the practice of a dispensary physician, surgeon, or member of the London or Dublin Society of Apothecaries.

6. Students of Medicine in the London schools, and in the school of the College of Surgeons in Dublin, can obtain there two *anni medici* out of the four required for the Edinburgh degrees in Medicine. One *annus medicus* may be constituted by attendance on Practical Anatomy and Hospital Practice during the winter session. Another *annus medicus* by attending either (a) full winter courses on any two of the following subjects:—Anatomy, Physiology, Chemistry, Pathology, Surgery, Medicine, Clinical Surgery, Clinical Medicine; or (b) on one such course and three months' courses on any two of the following subjects:—Botany, Practical Chemistry, Natural History, Medical Jurisprudence. If the student selects the arrangement prescribed in (a), certificates of attendance on either a third winter course, or a third three months' course, will also be accepted by this University. The other subjects, and the additional courses, not given in London or Dublin, required for the degrees of the University, will have to be attended at this University. In provincial schools, where there are no lecturers recognised by the University Court, a candidate can only have one *annus medicus*, and this is constituted by attendance on a qualified hospital along with a course of Practical Anatomy. All candidates not students of the University, availing themselves of the permission to attend the lectures of extra-academical teachers in Edinburgh, must at the commencement of each year of such attendance enrol their names in a book to be kept by the University for that purpose, paying a fee of the same amount as the matriculation fee paid by students of the University, and having, in respect of such payment, a right to the use of the library of the University. The fee for attendance on the lectures of an extra-academical teacher in Edinburgh, with a view to graduation, must be of the same amount as that exigible by medical professors in the University. No teacher is recognised who is at the same time a teacher of more than one of the prescribed branches of study, except in those cases where professors in the University are at liberty to teach two branches.

7. Every candidate must deliver, before the 31st day of March of the year in which he proposes to graduate, to the Dean of the Faculty of Medicine a declaration, in his own handwriting, that he has completed his twenty-first year, or that he will have done so on or before the day of graduation, and that he will not be, on the day of graduation, under articles of apprenticeship to any surgeon or other master; together with a statement of his studies, accompanied with proper certificates.

8. Each candidate is examined, both in writing and orally, on Chemistry, Botany, and Natural History; on Anatomy, Institutes of Medicine, Materia Medica (including Practical Pharmacy), and Pathology; on Surgery, Practice of Medicine, Midwifery, and Medical Jurisprudence; clinically on Medicine and on Surgery in a hospital. The examinations on Anatomy, Chemistry, Institutes of Medicine, Botany, Natural History, Materia Medica, and Pathology are conducted, as far as possible, by demonstrations of objects placed before the candidates.

<sup>11</sup> The Medical Faculty recommend that medical students should not attend Clinical Surgery during their first six months' attendance on Clinical Medicine.

9. Students who profess themselves ready to submit to an examination on the first division of these subjects, at the end of their second year may be admitted to examination at that time. Provided always that students who commence their medical studies in the summer session, and who profess themselves ready to submit to an examination on the first division of these subjects at the beginning of their second winter session may be admitted to examination at that time on condition that they produce certificates of attendance on at least two classes during each of two summer sessions and one winter session; and on the further condition that they shall not be admitted to a degree in Medicine unless their course of study, subsequent to the completion of the summer session in which they commence their medical studies, shall not be less than the minimum course of four years prescribed in Section 4 hereof.

10. Students who have passed their examination on the first division of these subjects may be admitted to examination on the second division at the end of their third year.

11. The examination on the third and fourth divisions cannot take place until the candidate has completed his fourth *annus medicus*.

12. Candidates may, if they choose, be admitted to examination on the first two of these divisions at the end of their third year, or to the fourth examinations at the end of their fourth year.

13. If any candidate at these examinations be found unqualified, he cannot be again admitted to examination unless he has studied during another year two of the prescribed subjects, either in the University or other medical school.

14. The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degrees of Bachelor of Medicine and Master in Surgery, and who is of the age of twenty-four years, and produced a certificate of having been engaged, subsequently to his having received the degrees of M.B. and C.M. for at least two years, in attendance on a hospital, or in the military or naval medical service, or in medical and surgical practice; provided always that the degree of M.D. shall not be conferred on any person unless he be a graduate in Arts of one of the universities of England, Scotland, or Ireland, or of such other universities as are above specified, or unless he shall before or at the time of his obtaining the degree of M.B., or thereafter, have passed a satisfactory examination on three of the subjects mentioned in Section II. of the statutes relative to preliminary examination. Two of these must be Greek, and Logic or Moral Philosophy, and the third is to be one of the following subjects, at the option of the candidate—namely, French, German, Higher Mathematics, and Natural Philosophy, and provided also that the candidate for the degree of M.D. shall submit to the Medical Faculty a thesis, certified by him to have been composed by himself, and which shall be approved by the Faculty, on any branch of knowledge comprised in the professional examinations for the degrees of M.B. and C.M., which he may have made a subject of study after having received that degree. The candidate must lodge his thesis with the Dean on or before 30th April of the year in which he proposes to graduate. No thesis will be approved by the Medical Faculty which does not contain either the results of original observations in practical medicine, surgery, midwifery, or in some of the sciences embraced in the curriculum for the Bachelor's and Master's degree; or else a full digest and critical exposition of the opinions and researches of others on the subject selected by the candidate, accompanied by precise references to the publications quoted, so that due verification may be facilitated.

15. Persons who began their medical studies before the 4th of February, 1861, are entitled to graduate under the system in force before or after that date, according as they may comply with the regulations in force in the University before or after that date.

The Preliminary Examinations in General Education are held in the Upper Library Hall, and students matriculated for the academic year are admitted on presenting their matriculation tickets at the door. Students matriculated for the summer only and non-matriculated students pay a fee of 10s. each, and are admitted on showing their receipts. Those who pay the fee in March will be admitted to the examination in October without further payment. Payment in October does not exempt from payment in March. The academic year is reckoned from 1st of November to 1st of November. Examinations on the preliminary branches of

extra-professional education will take place on the 3rd, 4th, 5th, and 6th October, 1882; and on the 13th, 14th, 15th, and 16th March, 1883.

The fees for M.B. and C.M., £22. Total fees and stamp for graduating as M.D. only, by regulations for students commencing before February, 1861, £25. The fees for examination must be paid at the secretary's office ten days before the dates thereof, and the fees for the degree of M.D., and the stamp duty for the latter, must be paid on or before the 15th day of July in the year of graduation. In the event of the candidate not passing any one of the professional examinations the fee is not returned; but he may appear at one subsequent examination without paying an extra fee, and at any future examination on paying one-half the fee.

The new buildings intended for the Faculty of Medicine of the University are now sufficiently advanced to admit of the departments of Institutes of Medicine and General Pathology being removed there for the ensuing winter session, in addition to the departments of Anatomy, Surgery, Practice of Physic, and Midwifery, which were carried on there during the past session.

#### UNIVERSITY OF GLASGOW.

Three degrees in Medicine are granted—viz., Bachelor of Medicine, Master in Surgery, and Doctor of Medicine. The curricula of study and the examinations for the several degrees conferred are nearly the same as in the University of Edinburgh. The annual term for conferring medical and surgical degrees is the 1st of August. The Preliminary Examinations of medical students in branches of general education take place on the 11th of October, 1882, and on the 28th of March, 1883.

The fees for the degrees are the same as in the University of Edinburgh.

The regulations under which the above degrees are granted and the notices of the subjects of examination may be obtained by application to the assistant clerk of Senate of the University.

*Bursaries tenable by Medical Students.*—Two James Ferguson Bursaries, value £70 per annum each, tenable for two years by medical students who have attended certain prescribed courses in the Arts Faculty. The Brisbane Bursary, of £50 yearly, held for four years by a student of medicine who is a Master of Arts. The Walton Bursary, of £36 yearly, held by a medical student (a native of England being preferred) for four years. The Logan Bursary, of £16 yearly, tenable by a medical student for four years. Two Rainy Bursaries, value £20 per annum each, open to medical students who have just completed the second year of professional study, and tenable for two years. The Armagh Bursaries, three in number, amounting each to £25 yearly, for three years, open to students of Divinity, Law, and Medicine, who have taken the degree of M.A. The Macfarlane Bursary, value £40 per annum, and tenable for three years, open to students who have attended the first session of their professional study in the University of Glasgow, and who have passed in all the seven subjects of the Preliminary Examination for M.B. The Marshall Bursary, value £17 per annum, and tenable for four years, open to students entering the Medical Faculty, and awarded by competition on the subjects of the Preliminary Examination. Four Limer Bursaries, two of the value of £25, and two of the value of £18 per annum each, tenable by medical students for three years.

#### UNIVERSITY OF ABERDEEN.

The curricula for the several degrees conferred are nearly the same as in the University of Edinburgh.

Professional Examinations will be held twice in each year—namely, in April and July, directly after the close of the winter and summer sessions.

The fees for graduation are the same as in the University of Edinburgh. Matriculation fee, including all dues, for the winter and summer sessions, £1; summer session alone, 10s.

Candidates who commenced their medical studies before November, 1861, are entitled to appear for examination for the degree of M.D., after four years' study, one of which must have been in the University of Aberdeen.

Besides the Royal Infirmary, students have the opportunity of attending the following institutions:—Sick Children's Hospital; General Dispensary, and Lying-in and Vaccine Institutions, daily; Royal Lunatic Asylum; Eye

Institution, in which is given clinical instruction on the Diseases of the Eye, and on the Application of the Ophthalmoscope for their diagnosis.

Application for further information should be addressed to Professor Brazier, Secretary to the Medical Faculty.

#### UNIVERSITY OF ST. ANDREWS.

Three degrees in Medicine are granted—namely, Bachelor of Medicine (M.B.), Master in Surgery (C.M.), and Doctor of Medicine (M.D.). The curricula for these degrees, and the regulations under which they are conferred, differ from those of the University of Edinburgh only in the particulars noticed below.

The degree of *Doctor of Medicine* may be conferred by the University of St. Andrews on any registered medical practitioner above the age of forty years whose professional position and experience are such as, in the estimation of the University, to entitle him to that degree, and who shall, on examination, satisfy the medical examiners of the sufficiency of his professional knowledge; provided always that degrees will not be conferred, under this section, on a greater number than ten in any one year. The examinations are held yearly, towards the end of April. Candidates must lodge with the Dean of the Medical Faculty the following certificates, along with application for admission to examination:—1. A certificate of age, being a baptismal certificate or an affidavit of age. 2. Holograph certificates from at least three medical men of acknowledged reputation in the medical profession or in the medical schools, recommending the candidate to the Senatus for the degree, and testifying to his professional skill and position. As only ten can graduate yearly, candidates will be selected whose service and certificates seem to the Medical Faculty to present the highest professional claims, and where these seem equal preference will be given to age and priority of application. 3. Candidates, when notified for examination, shall remit a portion of the graduation fee (viz., £10 10s.). This sum shall be forfeited should the candidate fail to appear, or to graduate, at the time appointed. 4. A satisfactory examination, written and *visà voce*, must be passed in the following departments—viz., *Materia Medica* and General Therapeutics, Medical Jurisprudence, Practice of Medicine and Pathology, Surgery, Midwifery, and Diseases of Women and Children.

No one will be received as a candidate for the degree of *Bachelor of Medicine* or *Master in Surgery* unless two years at least of his four years of medical and surgical study shall have been in one or more of the following universities or colleges—viz., the Universities of St. Andrews, Glasgow, Aberdeen, Edinburgh, Oxford, and Cambridge; Trinity College, Dublin; Queen's College, Belfast; Queen's College, Cork; and Queen's College, Galway.

Subject always to the condition here specified, the studies for candidates for the degrees of Bachelor of Medicine and Master in Surgery will be under the following regulations: The remaining years of medical and surgical study may be either in one or more of the universities and colleges above specified, or in the hospital schools of London, or in the school of the College of Surgeons of Dublin, or under such private teachers of medicine as may from time to time receive recognition from the University Court. Attendance during at least six winter months on the medical or surgical practice of a general hospital which accommodates at least eighty patients, and during the same period on a course of Practical Anatomy, may be reckoned as one of such remaining years. Attendance on the lectures of any private teacher in Edinburgh, Glasgow, or Aberdeen will not be reckoned for graduation in St. Andrews, if the fee for such lectures be of less amount than is charged for the like course of lectures in the University of Edinburgh, of Glasgow, or of Aberdeen, according as the teacher lectures in those places respectively.

Every candidate for examination for the degrees of M.B. and C.M. is required to lodge a declaration of age, a statement of his course of study, his inaugural dissertation, and all his certificates, with the Dean of the Medical Faculty, on or before the 25th of March in each year.

No candidate offering himself for examination on the first two divisions of the subjects specified in Clause 12 of the regulations will be considered to have passed in the second if he fails in the first; and no candidate offering himself for examination on the three divisions shall be considered to have passed in the third if he fails either in the first or second division. Every candidate who fails to pass in any of the

divisions will, for a first failure in any and each of the divisions, forfeit the sum of £2 2s., and £1 1s. for every subsequent failure in each.

#### UNIVERSITY OF DUBLIN (TRINITY COLLEGE).

**Matriculation.**—All students in the School of Physic intending to practise Physic must be matriculated, for which a fee of 5s. is payable. No student can be admitted for the winter course after Nov. 25th.

**Previous Medical Examination.**—Candidates for degrees and licences in Medicine and Surgery are required to pass a previous examination in Physics, Chemistry, Botany, Materia Medica and Pharmacy, and Descriptive Anatomy, and Institutes of Medicine (Practical Histology and Physiology) previous to their degree examination.

**Bachelor in Medicine.**—A candidate for this degree must be a graduate in Arts, and may obtain the degree of Bachelor in Medicine at the same commencement as that at which he receives his degree of B.A., or at any subsequent commencement. The medical education of a Bachelor in Medicine is of four years' duration, and comprises attendance on a single course of each of the following lectures:—Anatomy, Practical Anatomy, Surgery, Chemistry, Materia Medica and Pharmacy, Physiology, Practice of Medicine, Midwifery, Botany, Medical Jurisprudence, Heat, Electricity, Magnetism, Comparative Anatomy. Three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other metropolitan hospital recognised by the Board of Trinity College. Six months' instruction in Practical Midwifery, including Clinical Lectures. A certificate of personal attendance on Fever cases, with names and dates of cases. Six months' dissections, three months' laboratory instruction in Chemistry, and three months' Practical Histology are required. Any of the above-named courses may be attended at any medical school in Dublin recognised by the Provost and Senior Fellows. Fee for the *Licent ad Examinandum*, £5; for the M.B. degree, £11.

**Doctor in Medicine.**—A Doctor in Medicine must be M.B. of at least three years' standing, or have been qualified to take the degree of B.A. for three years, and must perform exercises for the degree before the Regius Professors of Physic, in accordance with the rules and statutes of the University. Total amount of fees for this degree, £13.

**Bachelor in Surgery.**—A Bachelor in Surgery must be a Bachelor in Arts and in Medicine, and have spent four years in the study of Surgery and Anatomy. He must also pass a public examination in the Hall before the Professors of the School of Physic, having previously completed the prescribed curriculum of study.<sup>12</sup> Candidates are required to perform surgical operations on the dead subject. Fee for the *Licent ad Examinandum*, £5; for the degree of Bachelor in Surgery, £5.

**Master in Surgery.**<sup>13</sup>—A Master in Surgery must be a Bachelor in Surgery of three years' standing, or have been qualified to take the degree of Bachelor in Surgery for three years; and must read a thesis publicly before the Regius Professor of Surgery, or undergo an examination before the Regius Professor, according to regulations to be approved by the Provost and senior Fellows. Fee for the degree of Master in Surgery, £11.

**University Licences.**—Candidates for the Licences in Medicine or Surgery must be matriculated in Medicine, and must have completed two years in Arts and four years in medical studies.

**Licentiate in Medicine.**—The medical course and examination necessary for the Licence in Medicine are the same as for the degree of M.B. A Licentiate in Medicine, on completing his course in Arts, and proceeding to the degree of B.A., may become a Bachelor in Medicine, on paying the degree fees, without further examination in Medicine. Fee for the *Licent ad Examinandum*, £5; for the Licence in Medicine, £5.

**Licentiate in Surgery.**—The surgical course and examination necessary for the Licence in Surgery are the same as for the degree of Bachelor in Surgery. Fee for the *Licent ad Examinandum*, £5; for the Licence in Surgery, £5.

**Medical Scholarships.**—Two Medical Scholarships will be given annually, tenable for two years, with a salary of £20

<sup>12</sup> Students in the School of Physic who matriculated before June 22nd, 1872, may obtain the degree of Master in Surgery according to the regulations in force previous to the creation of the degree of Bachelor in Surgery.

<sup>13</sup> Masters in Surgery must be of the standing of Masters of Arts.

per annum, on the conditions stated in the University Calendar.

**Qualification in State Medicine.**—Doctors in Medicine or graduates in Medicine and Surgery of Dublin, Oxford, or Cambridge, who wish to obtain from the University a Certificate of Qualification in State Medicine, can do so on passing an examination in a limited course of the following subjects:—1. Law, comprehending sanitary legislation, and the laws relating to the conduct and duties of medical men. 2. Engineering in its sanitary aspects. 3. Pathology, including the laws of epidemics, vaccination, insanity, &c. 4. Vital and sanitary statistics. 5. Chemistry in relation to air, water, gaseous poisons, deodorisation, and disinfection. 6. Meteorology. 7. Medical Jurisprudence. 8. Hygiene.

The total cost of the education and first degrees in Medicine and Surgery is as follows, in addition to the fees for education in Arts and B.A. degree (£83 4s.); Medical and Surgical Lectures, £59 1s.; Hospitals, £42 2s.; Medical and Surgical Examinations and Degrees, £31.

#### ROYAL UNIVERSITY OF IRELAND.

In the commencement of the year the Queen's University in Ireland ceased to exist, and the Queen's Colleges became dissociated from the University. The Colleges still remain as heretofore great teaching centres, more particularly for medical education, and it is gratifying to find that their progress has been so uninterrupted since their establishment in 1849. During the last year it was believed that the loss of certain privileges in relation to the Queen's University would have had an injurious effect on the number of students entering their walls, but it is satisfactory to learn that these fears are unfounded, and that never were the Queen's Colleges in Ireland so healthy and vigorous as at the present moment. The Royal University of Ireland, which takes the place of the late Queen's University, has so far succeeded in its aims and objects, and will no doubt attract a very large number of medical students, who, from various circumstances, pecuniary and otherwise, could not comply with the regulations of the late and other universities. The standard selected by the new University is a high one, and we believe that the Royal University of Ireland will prove of immense service to medical education in Ireland. A medical student from the Queen's Colleges, the Queen's University, or any other institution approved by the Senate, matriculated therein before October 1st, 1891, who has completed at least one year of the medical curriculum in any of the said colleges, is entitled to credit for any year's course in the Royal University, without passing the First Examination in Arts. To put it plainly, all examinations passed by students of the Queen's Colleges are allowed for in the Royal University. The cost of lectures for the M.B., M.D., and M.Ch., with fees for examinations, will come to about £65, which, compared with other universities, permits medical degrees to be obtained by parties to whom an expensive curriculum would be a serious obstacle. The University differs from the Queen's University in granting a M.B. degree, and there is also a diploma in Sanitary Science, which is to be conferred only on graduates in Medicine of the University, at a fee of £2. There will be about 600 candidates for the Matriculation Examination to be held this month.

#### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

The licence of this College is a qualification to practise Medicine, Surgery, and Midwifery, and is recognised by the Local Government Board as a qualification in Surgery as well as in Medicine.

**Licentiate.**—Every candidate for the College licence (except when otherwise provided by the by-laws) is required to produce satisfactory evidence to the following effect:—Of having attained the age of twenty-one years. Of moral character. Of having passed before the commencement of professional study an examination in the subjects of general education recognised by the General Medical Council. Of having been registered as a medical student in the manner prescribed by the General Medical Council. "Every candidate (not exempted from registration) is required to have been registered at least forty-five months previously to admission to the Final Examination." Of having been engaged in professional studies during at least forty-five months, of which at least three winter sessions and two summer sessions

shall have been passed at a recognised medical school or schools, and one winter session and two summer sessions in one or other of the following ways:—

1. Attending the practice of a hospital or other institution recognised by the College for that purpose. 2. Receiving instruction as the pupil of a legally qualified practitioner having opportunities of imparting a practical knowledge of Medicine, Surgery, or Midwifery. 3. Attending lectures on any of the required subjects of professional study at a recognised place of instruction. Professional studies commenced before Registration, except in the subjects of the First Examination, will not be recognised by the College. Of having attended, during three winter sessions and two summer sessions, the medical and surgical practice at a recognised hospital or hospitals;<sup>14</sup> of having discharged the duties of a medical clinical clerk during six months; and of surgical dresser during other months; and of having been engaged during six months in the clinical study of Diseases peculiar to Women. Of having received instruction in Chemistry, Practical Chemistry, Materia Medica, Botany, and Practical Pharmacy. Of having attended a course of lectures on the following subjects:—Anatomy (with Dissections), during twelve months; Physiology; a practical course of General Anatomy during a winter or a summer session, consisting of not less than thirty meetings of the class; Pathological Anatomy; Principles and Practice of Medicine; Principles and Practice of Surgery; Midwifery and the Diseases peculiar to Women; Forensic Medicine. Of having attended Clinical Lectures on Medicine during nine months, and also Clinical Lectures on Surgery during nine months, and of having been engaged during a period of three months in the Clinical Study of Diseases peculiar to Women. Of having passed the professional examinations.

Any candidate who shall produce satisfactory evidence of having passed an examination on Anatomy and Physiology, conducted by a university in the United Kingdom, in India, or in a British colony, or by the College of Surgeons in England, Scotland, or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, shall be exempt from re-examination on those subjects. Any candidate who shall produce satisfactory evidence of having passed an examination on Chemistry and Materia Medica, required for a degree in Medicine at a university in the United Kingdom, in India, or in a British colony, will be exempted from re-examination on those subjects. Any candidate who shall have obtained a degree in Surgery at a university in the United Kingdom, after a course of study and an examination satisfactory to the College, shall be exempt from re-examination on Surgical Anatomy, and on the Principles and Practice of Surgery. Any candidate who shall have passed the examination on Surgery conducted by the Royal College of Surgeons of England, or the Royal College of Surgeons of Edinburgh, or the Royal College of Surgeons in Ireland, or the Faculty of Physicians and Surgeons of Glasgow, after a course of study and an examination satisfactory to the College, shall be exempt from re-examination on Surgical Anatomy, and on the Principles and Practice of Surgery. Any candidate, being a "registered medical practitioner," whose qualification or qualifications shall have been obtained before the first day of January, 1861, having been with the consent of the College admitted a candidate for the licence, will be examined on the Principles and Practice of Medicine, Surgery, and Midwifery; but he will be exempted from such other parts of the professional examinations as his qualifications may seem to the examiners to render in his case unnecessary. Any candidate who shall have obtained a foreign qualification which entitles him to practise Medicine or Surgery in the country where such qualification has been conferred, after a course of study and an examination equivalent to those required by the regulations of the College, shall, on production of satisfactory evidence as to age, moral character, and proficiency in vaccination, be admissible to the Pass Examination, and shall be exempt from re-examination on such subjects as shall in each case be considered by the Censors' Board to be unnecessary.

Examinations will take place in the months of January, April, July, and October, and no candidate can be admitted without a fortnight's notice.

**Members.**—The members of the College, present and future, shall be alone eligible to the fellowship. Every

candidate (except such as are admissible under special provisions relating to practitioners) must produce proof of his having been engaged in professional studies during a period of five years. The examination will be partly written and partly *viva voce*. Doctors and Bachelors of Medicine may claim exemption from all or any part of the examination, except such as relate to the Third or Pass Examination. Any candidate who shall produce satisfactory evidence of having passed an examination on Anatomy and Physiology, conducted by any of the bodies named in Schedule A to the Medical Act and recognised by the College as requiring a course of study and an examination satisfactory to the College, will be exempt from re-examination on the subjects of the Primary Examinations. Any candidate who shall have obtained a degree in Surgery, at a university in the United Kingdom, after a course of study and an examination satisfactory to the College, will be exempt from re-examination on Surgical Anatomy and the Principles and Practice of Surgery. Any candidate who shall have passed the examination on Surgery conducted by the Royal College of Surgeons of England, or the Royal College of Surgeons of Edinburgh, or the Royal College of Surgeons in Ireland, or the Faculty of Physicians and Surgeons of Glasgow, after a course of Study and an examination satisfactory to the College, will be exempt from re-examination on Surgical Anatomy and on the Principles and Practice of Surgery. Every candidate approved by the Censors' Board shall be proposed at the next general meeting of fellows as qualified to become a member of the College.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

### REGULATIONS RESPECTING THE EDUCATION AND EXAMINATION OF CANDIDATES FOR THE DIPLOMA OF MEMBER OF THE COLLEGE.

**Preliminary General Education and Examination.**—Candidates are required, before the commencement of their professional education, to pass a Preliminary Examination recognised by the General Medical Council and to obtain a certificate of having been registered by that Council. N.B. In the case of any colonial, Indian, or foreign student, not registered by the General Medical Council, the conditions of admission to the Professional Examinations for the diploma will be determined by the Council of the College.

**Professional Education.**—The following are recognised modes of commencing professional education:—(1) Attendance on the practice of a hospital, or other public institution recognised by this College for that purpose. (2) Instruction as the pupil of a legally qualified surgeon, holding the appointment of surgeon to a hospital, general dispensary, or union workhouse, or where such opportunities of practical instruction are afforded as shall be satisfactory to the Council. (3) Attendance on lectures on Anatomy, Physiology, or Chemistry, by lecturers recognised by this College.

Candidates, prior to their admission to the First or Primary Examination on Anatomy and Physiology, will be required to produce the following certificates, viz.:—Of having, prior to the commencement of professional study, been registered by the General Medical Council. Of having attended lectures on Anatomy during two winter sessions. Of having performed dissections during not less than two winter sessions. Of having attended lectures on General Anatomy and Physiology<sup>15</sup> during one winter session. Of having attended a Practical Course of General Anatomy and Physiology<sup>16</sup> during another winter or a summer session, consisting of not less than thirty meetings of the class.

Candidates, prior to their admission to the Second or Pass Examination on Surgical Anatomy and the Principles and Practice of Surgery, Medicine, and Midwifery, will be required to produce the following certificates, viz.:—Of being twenty-one years of age. Of having been engaged, subsequently to the date of registration by the General Medical Council, during four years, or during a period extending over not less than four winter and four summer sessions, in the acquirement of professional knowledge. Of having attended lectures on Surgery during one winter session. Of having

<sup>15</sup> By the Practical Course referred to in Clause 5, it is meant that the learners themselves shall, individually, be engaged in the necessary experiments, manipulations, &c.; but it is not hereby intended that the learners shall perform dissections.

<sup>14</sup> A three months' course of clinical instruction in the wards of a recognised lunatic hospital or asylum may be substituted for the same period of attendance in the medical wards of a general hospital.

<sup>16</sup> The certificates of attendance on the several courses of lectures must include evidence that the student has attended the practical instructions and examinations of his teacher in each course.

attended a course of Practical Surgery during a period occupying not less than six months prior or subsequent to the course required by the preceding Clause 3.<sup>17</sup> Of having attended one course of lectures on each of the following subjects, viz.:—Chemistry,<sup>18</sup> *Materia Medica*, Medicine, Forensic Medicine, Midwifery (with practical instruction), and a certificate of having personally conducted not less than ten labours, and Pathological Anatomy during not less than three months. Of having studied Practical Pharmacy during three months. Of having attended a three months' course of Practical Chemistry (with manipulations), in its application to medical study. Of instruction and proficiency in the practice of Vaccination.<sup>19 20</sup> Of having attended, at a recognised hospital or hospitals, the Practice of Surgery, during three winter<sup>21</sup> and two summer<sup>22</sup> sessions. Of having been individually engaged, at least twice in each week, in the observation and examination of patients at a recognised hospital or hospitals, under the direction of a recognised teacher, during not less than three months.<sup>23</sup> Of having, subsequently to the first winter session of attendance on Surgical Hospital Practice, attended at a recognised hospital or hospitals, clinical lectures on Surgery, during two winter and two summer sessions. Of having been a dresser at a recognised hospital, or of having, subsequently to the completion of one year's professional education, taken charge of patients under the superintendence of a surgeon during not less than six months, at a hospital, general dispensary, or parochial or union infirmary recognised for this purpose, or in such other similar manner as, in the opinion of the Council, shall afford sufficient opportunity for the acquirement of Practical Surgery. Of having attended during the whole period of attendance on Surgical Hospital Practice (see Clause 9) demonstrations in the post-mortem rooms of a recognised hospital. Of having attended at a recognised hospital or hospital, the practice of Medicine, and Clinical Lectures on Medicine, during one winter and one summer session.

*Special Notice.*—Candidates commencing their professional education on or after the 1st of October, 1882, will not be admitted to the Second or Pass Examination until after the expiration of two years from the date of their passing the Primary or Anatomical and Physiological Examination for such diploma, except in the following cases:—When a candidate, before presenting himself for the Primary Examination, shall possess a recognised degree or diploma in Medicine or Surgery, or shall have completed the curriculum of professional education for the diploma. In the case of a candidate who, being desirous of obtaining the Fellowship, shall fail to present himself for the Primary Examination for the Membership at the end of his second year of professional study, but who shall pass at the end of his third winter session the Primary Examination for the Fellowship, it being required in such case that not less than one year of attendance on the Surgical Practice of a recognised hospital shall intervene between the date of his passing the Primary Examination for the Fellowship and the date of his presenting himself for the Second or Pass Examination for the diploma of Member. In the case of a candidate who, having commenced his professional studies by attendance on the practice of a recognised provincial or colonial hospital, and having completed a year of such attendance shall fail to pass the Primary Examination at the end of his second winter session of attendance at a recognised medical school, provided that in his case not less than one year shall elapse between the

date of his passing the Primary Examination and the date of his presenting himself for the Second or Pass Examination for the diploma of Member. When a candidate owing to illness, duly certified by one or more of the teachers of his medical school, shall be prevented from presenting himself for the Primary Examination on the completion of his second year of professional study. And in the case of a candidate who, from some unforeseen circumstances, shall fail to present himself for the Primary Examination on the completion of his second year of professional study, it being left to the Court of Examiners to determine whether in such case the candidate shall or shall not be required to comply with the regulation.

Certificates of attendance upon the practice of a recognised provincial or colonial hospital unconnected with, or not in convenient proximity to, a recognised medical school, will not be received for more than one winter and one summer session of the hospital attendance required by the regulations of this College; and in such cases Clinical Lectures will not be necessary, but a certificate of having acted as dresser for a period of at least six months will be required. Those candidates who shall have pursued the whole of their studies in Scotland or Ireland will be admitted to examination upon the production of the several certificates required respectively by the College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, and the College of Surgeons in Ireland from candidates for their diploma, together with a certificate of instruction and proficiency in the practice of Vaccination, and satisfactory evidence of having been occupied, subsequently to the date of registration by the General Medical Council, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge; and in case of candidates who shall have pursued the whole of their studies at recognised foreign or colonial universities, upon the production of the several certificates required for their degree by the authorities of such universities, together with a certificate of instruction and proficiency in the practice of Vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the Preliminary Examination, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge. Members or Licentiates of any legally constituted College of Surgeons in the United Kingdom, and Graduates in Surgery of any University recognised for this purpose by this College, will be admitted to examination on producing their diploma, licence, or degree, together with proof of being twenty-one years of age, a certificate of instruction and proficiency in the practice of Vaccination, and satisfactory evidence of having been occupied, subsequently to the date of registration by the General Medical Council, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge. Graduates in Medicine of any legally constituted College or University recognised for this purpose by this College will be admitted to examination on adducing, together with their diploma or degree, proof of being twenty-one years of age, a certificate of instruction and proficiency in the practice of Vaccination, and satisfactory evidence of having been occupied, subsequently to the date of registration by the General Medical Council, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge.

*Professional Examination.*—This Examination is divided into two parts. The first or Primary Examination, on Anatomy and Physiology, is partly written and partly demonstrative on the recently dissected subject, and on prepared parts of the human body. The second or Pass Examination, on Surgical Anatomy and the Principles and Practice of Surgery, Medicine, and Midwifery,<sup>24</sup> is partly written, partly oral, and partly on the practical use of

<sup>17</sup> The course of Practical Surgery referred to in Clause 4 is intended to embrace instruction in which each pupil shall be exercised in practical details, such as in the application of anatomical facts to surgery, on the living person, or on the dead body; the methods of proceeding and the manipulations necessary in order to detect the effects of diseases and accidents on the living person, or on the dead body; the performance, where practicable, of the operations of surgery on the dead body; the use of surgical apparatus; the examination of diseased structures, as illustrated in the contents of a museum of morbid anatomy and otherwise.

<sup>18</sup> The course of lectures on Chemistry included in Clause 5 will not be required in the case of a candidate who shall have passed a satisfactory examination in this subject in his preliminary examination.

<sup>19</sup> The certificate of instruction in Vaccination must be such as will qualify its holder to contract as a Public Vaccinator under the Regulations at the time in force of the Local Government Board.

<sup>20</sup> The certificates of attendance on the several courses of lectures must include evidence that the student has attended the practical instructions and examinations of his teacher in each course.

<sup>21</sup> The winter session comprises a period of six months, and, in England, commences on the 1st of October and terminates on the 31st of March.

<sup>22</sup> The summer session comprises a period of three months, and, in England, commences on the 1st of May and terminates on the 31st of July.

<sup>23</sup> It is intended that the candidate should receive the instruction required by Clause 10 at an early period of his attendance at the hospital.

<sup>24</sup> Candidates can claim exemption from examination in Medicine and Midwifery under the following conditions, viz.:—The production by the candidate of a degree, diploma, or licence in medicine and midwifery entitling him to register under the Medical Act of 1858, or a degree, diploma, or licence in medicine and midwifery of a colonial or foreign university approved by the Council of the College. A declaration by the candidate, prior to his admission to the Pass Examination, that it is his intention to obtain either of the qualifications in medicine and midwifery mentioned in the foregoing paragraph, in which case the diploma of the College will not be issued to him until he shall produce either the said qualification, or proof of having passed the several examinations entitling him to receive the same.

surgical apparatus, and the practical examination of patients.

The Primary Examinations are held in the months of January, April, May, July, and November, and the Pass Examinations generally in the ensuing week, respectively. Candidates will not be admitted to the Primary Examination until after the termination of the second winter session of their attendance at a recognised school or schools; nor to the Pass, or Surgical Examination, until after the termination of the fourth year of their professional education. The fee of five guineas, paid prior to the first admission to the Primary Examination, is retained whether the candidate pass or fail to pass the examination, but is allowed as part of the whole fee of twenty-two pounds<sup>25</sup> payable for the diploma. A candidate, after failure at any Primary Examination, is required, on admission to any subsequent Primary Examination, to pay a further fee of three guineas, which is retained, whether he pass or fail to pass the examination, and which further fee is not allowed as part of the whole fee of twenty-two pounds for the diploma.

The fee of sixteen pounds fifteen shillings is payable prior to each admission to the Pass Examination; but on each occasion of failure the balance of eleven pounds ten shillings is returned to the candidate. A candidate having entered his name for either the Primary or Pass Examination, who shall fail to attend, will not be allowed to present himself for examination within the period of three months from the date at which he shall have so failed to attend. A candidate referred on the Primary Examination is required, prior to his admission to re-examination, to produce a certificate that he has pursued, to the satisfaction of his teachers, his anatomical and physiological studies in a recognised medical school during not less than three months subsequently to the date of his reference. A candidate referred upon the Primary Examination, who shall not obtain more than half of the total minimum number of marks, is not readmitted to examination until after the lapse of six months, and is then required to produce a certificate of the performance of dissections during not less than three months, and of having pursued, to the satisfaction of his teachers, his anatomical and physiological studies in a recognised medical school during six months subsequently to the date of his reference. A candidate referred on the Pass Examination is required, unless the Court of Examiners shall otherwise determine, to produce, prior to his admission to re-examination, a certificate of at least six months' further attendance on the surgical practice of a recognised hospital, together with lectures on clinical surgery, subsequently to the date of his reference. A candidate, referred on the Pass or Surgical Examination for the diploma of Member, who shall have exhibited such extreme ignorance in the examination as, in the opinion of the Court of Examiners, to render it desirable that he should be referred for a longer period than six months, is required, before his admission to re-examination, to produce a certificate of having attended the surgical practice and clinical lectures on Surgery of a recognised hospital for a further period of nine or twelve months, as the Court shall determine.

#### ROYAL COLLEGE OF PHYSICIANS, EDINBURGH.

**The Licence.**—No one can obtain the licence of the College until he has completed the age of twenty-one years. Every applicant for the licence must produce evidence that he has been engaged in the study of Medicine during a period of at least four years subsequent to his registration as a medical student, which period shall include attendance during not less than four winter sessions, or three winter and two summer sessions, at a recognised medical school. He must produce certificates that he has attended the following courses at a university, or at some medical school recognised by the College:—Anatomy, six months; Practical Anatomy, six months; Chemistry, six months; Practical Chemistry, three months; Materia Medica and Pharmacy, three months; Physiology or Institutes of Medicine, three months; Practice of Medicine, six months; Clinical Medicine, six months; Principles and Practice of Surgery, six months; Clinical Surgery, three months; Midwifery, three months; Medical Jurisprudence, three months; General Pathology or Patho-

logical Anatomy, three months; Practical Pharmacy, three months. The applicant must also produce evidence of having attended the practice of a public hospital (containing not fewer than eighty beds) during a period of not less than twenty-four months, twelve of which must have been spent in attendance on the medical wards. He must have attended for six months the practice of a public dispensary, or have acted for six months as clinical clerk or dresser in a hospital, or have been engaged for six months as visiting assistant to a registered practitioner. He must produce a certificate of having attended at least six cases of Labour under the superintendence of a qualified medical practitioner, and that he has studied Vaccination under a competent and recognised teacher.

No candidate will be admitted to the first examination until the end of his second winter session, or to the second until he has completed four years of professional study. The examinations will be conducted partly *vivâ voce*, partly by written papers. Candidates for the licence of the College who have passed the first Professional Examination before a qualified body (provided it be as extensive as that required by this College) will be at once admitted to the second part of the examination.

Meetings for the examination of candidates, who already possess a qualification from a recognised licensing body, will be held on the first Wednesday of every month (with the exception of September and October), and, if necessary, on the following days. No one is admissible to examination who has within the previous three months been rejected by any licensing board. The fee for the licence is fifteen guineas.

Candidates may be admitted to Special Examination on days other than those appointed above on bringing forward reasons satisfactory to the Council, and on paying an extra fee of five guineas. Should the candidate be unsuccessful, the sum of eleven guineas will be returned to him.

**The Membership.**—Any licentiate of a College of Physicians, or Graduate of a British or Irish University, with whose knowledge of Medical and General Science the College may be satisfied, may be admitted a Member of the College, provided he shall have attained the age of twenty-four years.

**The Fellowship.**—No one shall be elected a Fellow of the College until he has been at least one year a Member thereof, and has attained the age of twenty-five years.

The following additional regulations apply to all candidates whose petitions are received after March 1st, 1882:—

Every candidate for the Membership (except in the case of medical practitioners of ten years' standing, distinguished for scientific attainments, whom the Council may see fit to exempt) shall be required to pass an examination.—On the Principles and Practice of Medicine, including Therapeutics. On one of the following subjects to be selected by the candidate:—(a) Pathology, including Morbid Anatomy; (b) Medical Jurisprudence and Public Health; (c) Midwifery and the Diseases of Women; (d) Psychological Medicine.

The fee to be paid by a member is £31 10s. When a licentiate is raised to the rank of a member, he pays £21. When a member is raised to the rank of a fellow, the fee is £31 10s., exclusive of stamp duty, which amounts to £25. All candidates for fellowship or membership must lodge their fees, and the amount of stamp duty payable at the time to Government, with the treasurer, previously to presenting their petitions.

**Qualification in Public Health.**—The College now confers certificates of competency in Public Health. Examinations are held in April and October. Fee for certificate, £10 10s.

#### ROYAL COLLEGE OF SURGEONS, EDINBURGH.

Every candidate for a surgical diploma must have followed his course of study in a university or in an established school of medicine, or in a provincial school specially recognised by the College of Surgeons of that division of the United Kingdom in which it is situate.

**Preliminary Examination.**—All students who intend becoming candidates for the diploma of the College must have passed the complete examination in general education as prescribed by the General Medical Council, and have had their names inscribed in the Register of Medical Students at the commencement of their professional studies. Examinations will be held on Oct. 14th, 16th, and 17th, 1882; April 10th, 11th, and 12th; July 6th, 7th, and 9th; Oct. 13th, 15th, and 16th, 1883. Testimonials of proficiency granted by educational bodies recognised by the

<sup>25</sup> This sum of £22 is exclusive of the fee of £2 paid for the Preliminary Examination.

Medical Council exempt students from the Preliminary Examination.

**Professional Examination.**—Candidates are subjected to two Professional Examinations, conducted at separate sittings, partly in writing and partly orally.

The First Examination embraces Anatomy, Physiology, and Chemistry. Examinations will be held Oct. 17th, 1882; Jan. 23rd, March 27th, April 17th, July 17th, 1883.

Candidates who desire to pass the First Professional Examination must apply to the Secretary on or before the Friday preceding the day of examination, and must produce certificates of attendance in regard to all those courses of study which have reference to the subjects of that examination. They must also produce evidence of having passed the Preliminary Examination. The sum of £6 6s. must be paid to the treasurer of the College for this examination not later than 9 A.M. of the Saturday preceding it. This sum will be considered as paid to account of the entire fee of £15 15s. payable for the diploma.

The Second Examination embraces Surgery and Surgical Anatomy; also Medicine, Midwifery, Materia Medica, and Medical Jurisprudence; and does not take place before the termination of the winter session of the last year of study; in the case of candidates who began their course of study after 16th of September, 1882, it will not take place till forty-five months after the examination in general education.

Application for examination must be made to the secretary not later than the Monday previous to the day of the examination.

Every candidate must produce to the secretary—1. Satisfactory evidence of his having attained the age of twenty-one years, and of having been duly registered. 2. The certificates of his classes. 3. The certificate of his having passed the First Professional Examination. 4. A tabular statement (for which a printed form will be furnished) exhibiting the full amount of his professional education, and distinguishing the classes, hospitals, dispensaries, and schools attended during each session of his studies. If he have been an apprentice, he must also insert the name of his master, the date of his indenture, and the length of time for which he is bound. This statement, accurately filled up, must be attested by his signature, and afterwards delivered by the candidate to the officer of the College, to be preserved by the College. If the candidate have been an apprentice to a Fellow of the College, he must also produce his discharged indenture.

The remaining fee payable to the College (being £9 9s.), together with the receipt for the fee paid for the First Professional Examination, must be lodged, not later than 9 A.M. of the Tuesday preceding the examination day, in the hands of the treasurer. £5 5s. will be returned to unsuccessful candidates.

Candidates who have passed the First Examination in Anatomy, Physiology, and Chemistry, at any of the licensing boards recognised by the Medical Act, will be admissible to the Second Professional Examination on producing certificates of the whole course of study, of having passed their Preliminary and First Professional Examinations, and of having been registered. If any of the three subjects of the first examination have been omitted, such candidates will have to undergo the first examination on the omitted subjects; and none of the subjects set done will be omitted at the second examination, even if some of them should have formed part of the first examination by another board. The fee is £15 15s. Unsuccessful candidates under this regulation receive back £11 11s.

In order to test more effectually the practical knowledge of candidates, recent dissections, anatomical specimens, and articles of the *materia medica* will be employed during the examinations; and all candidates will be required to write out formulæ of prescriptions. They will also be subjected to a practical clinical examination in the surgical hospital, including the application of surgical apparatus, &c.

No candidate will be admissible to examination who has been rejected by any other licensing board within the three months preceding his application to be examined.

**The Dental Diploma.**—Every candidate for the Dental Diploma must have attended the general lectures and courses of instruction required at a University or an established medical school recognised by the College as qualifying for the diploma in Surgery. The special courses of instruction may have been followed in a recognised dental hospital or school, or by teachers recognised by the College. The examinations will be both written and oral, and be

conducted in the same manner as the ordinary surgical examinations.

Candidates for the Dental Diploma must produce evidence of having attained the age of twenty-one years, and will be required to produce a certificate of having passed the Preliminary Examination in General Education required for the ordinary licence in Surgery, or an examination equivalent to this, and recognised by the General Medical Council, except in the case of candidates who shall have commenced their professional education previous to the first day of August, 1878.

Candidates will also be required to produce certificates of having been engaged during four years in the acquirement of professional knowledge, and of having been during that period, or at some time previous to their examination, engaged for not less than three years in the acquirement of a practical knowledge of Mechanical Dentistry with a practitioner registered under this Act. Lectures and other courses of instruction must have been attended at a recognised medical school, and the number of lectures in each of the general courses must correspond with those required for the Surgical Diploma of the College. The fee for the diploma is £10 10s.

#### ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH.

The Royal College of Physicians of Edinburgh, and the Royal College of Surgeons of Edinburgh, while they still continue to give their diplomas separately, under separate regulations, have made arrangements by which, after one series of examinations, the student may obtain the diplomas of both Colleges. The general principle of this joint examination is, that it shall be conducted by a board in which each body is represented in those branches which are common to both medicine and surgery; but that the College of Physicians shall take exclusive charge of the examination in Medicine, and the College of Surgeons of the examination in Surgery. The object of the joint examination is to give to students facilities for obtaining from two separate bodies, and at less expense, a qualification in Medicine and a qualification in Surgery. Students passing that examination successfully will be enabled to register two qualifications under the Medical Act—Licentiate of the Royal College of Physicians of Edinburgh, and Licentiate of the Royal College of Surgeons of Edinburgh. The arrangement for thus conferring a double qualification by the co-operation of the two Colleges is in conformity with Section 19 of the Medical Act, and has received the special sanction of the General Council of Medical Education and Registration.

#### FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

Preliminary Examinations in General Literature, in accordance with the regulations of the General Council, will be held in the Faculty Hall during the session 1882-83 on the following Fridays, commencing at 9 o'clock—namely, October 20th, 1882, March 30th, June 29th, and September 7th, 1883; and on each occasion the examination will be continued on the succeeding day. Those who are unsuccessful may appear at one subsequent examination without paying a second fee. The fee for the examination and certificate is 10s.

The course of study for the diploma and the regulations generally correspond with those required by the Royal College of Surgeons of Edinburgh.

The Professional Examinations are held at four periods in 1882—in January, April, July, and October. The following are the dates at which the first examination will begin in 1882-83: Oct. 18th, 1882; Jan. 9th, April 6th, July 18th, 1883. The second examination will commence on Oct. 23rd, 1882; Jan. 15th, April 10th, and July 23rd, 1883. Candidates will not be admitted to the final examination until the expiry of forty-five months from the date of registration, which period must embrace at least three winter and two summer sessions, or four winter sessions, of study at a medical school.

The regulations regarding examinations are nearly similar to those of the Royal College of Surgeons of Edinburgh. All candidates at the Primary Examination are required to dissect in presence of the examiners.

The fee for the diploma is fifteen guineas—six guineas for the first and nine guineas for the second examination. Car-

didates not already qualified in Medicine are examined in that subject orally and clinically, as well as by written papers.

#### REGULATIONS REGARDING THE DOUBLE QUALIFICATION.

The Faculty of Physicians and Surgeons of Glasgow and the Royal College of Physicians, Edinburgh, grant their diplomas conjointly before a board of examiners in which each body is represented, the object being to give to students facilities for obtaining from two separate bodies, and at less expense, a double qualification in Medicine and Surgery. Students passing this examination successfully will be enabled to register two qualifications under the Medical Act—namely, Licentiate of the Faculty of Physicians and Surgeons of Glasgow, and Licentiate of the Royal College of Physicians of Edinburgh. The curriculum of study embraces a course of Medicine, in addition to the subjects required for a diploma of the Faculty. The fee for the first examination is eight guineas; for the second twelve guineas.

The examination for the Double Qualification will begin in the Faculty Hall, Glasgow, at the following periods—namely, first examination, October 18th, 1882; January 9th, April 6th, July 18th, 1883. The second examination will begin on October 26th, 1882; January 18th, April 16th, and July 6th, 1883.

Applications to be admitted to either the first or second examination must be made to the Secretary of the Faculty not later than one week preceding the examination.

Candidates are required to subscribe a declaration that they have not been rejected by any examining board within three months before the examination.

The other regulations are nearly the same as those for the diploma of the Faculty.

#### KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

Examinations in the subjects of the First Professional Examination are held quarterly, in January, April, July, and October. Examinations in the subjects of the Final Examination for the licence in Medicine of the College and for the licence in Midwifery are held in the week following the first Friday in each month, except August and September. Every candidate for a licence must return his name to the Registrar of the College, and lodge with him his certificates, bank (Royal Bank of Ireland) receipt of fees, and his schedule, at least four days before the first Friday in each month. Special examinations will be held at such times as the President may appoint.

*Licence in Medicine.*—Every candidate for the licence of the College to practise Medicine must produce satisfactory evidence—1. Of character, from a Fellow of the College, or from two registered practitioners. 2. Of having passed an examination in general education, held by some one of the examining bodies recognised by the General Medical Council. 3. Of having been engaged during a period of four years in the study of Medicine. 4. Of having attended courses of lectures on the following subjects, at schools recognised by the College: Practical Anatomy, two courses; Physiology or Institutes of Medicine, Chemistry, Practical Chemistry, Materia Medica, Medical Jurisprudence, Practice of Medicine and Pathology, Surgery, and Midwifery—each one course. 5. Of having attended for twenty-seven months a recognised Medico-Chirurgical Hospital, in which clinical lectures and clinical instruction in Medicine are given, the attendance not to be for more than nine months in any one year—viz., six winter, and three summer months—for not less than three months. 6. Of having studied Fever in a recognised clinical hospital, containing fever wards, and recorded from daily personal observation at least five cases of fever, to the satisfaction of the attending clinical physician, as attested by his signature.<sup>26</sup> 7. Of having attended Practical Midwifery and Diseases of Women for six months at a Lying-in Hospital or Maternity recognised by the College; or, where such hospital attendance cannot have been obtained during the course of study, of having been engaged in Practical Midwifery under the supervision of a registered practitioner holding public appointments; in either case not less than twenty labour cases must have been actually attended. 8. Of having lodged the admission fee

in the Royal Bank of Ireland, Foster-place, to the credit of the College.

The professional examination is divided into two parts: 1. Anatomy, Physiology, Chemistry, and Materia Medica. 2. Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics. Candidates may be examined in the subjects of the first part at the termination of the second year of study, on producing the certificates in these subjects, or in all the subjects of their education, on the completion of their medical studies. No candidate can be examined in the subjects of the first and second parts in the same month.

Candidates qualified as follows are required to undergo the second part only of the professional examination, viz.:—(1) Graduates in Medicine of any University in the United Kingdom, or of any Foreign University approved by the College; (2) Fellows, Members, or Licentiates of the Royal College of Physicians of London or Edinburgh; (3) Graduates or Licentiates in Surgery; (4) Candidates who, having completed the curriculum laid down above, shall have passed the previous professional examination or examinations of any of the licensing medical authorities in the United Kingdom. Candidates qualified, as specified in Sections 1, 2, and 3, must fill up a schedule and present their registration certificate (or their medical or surgical qualification), as well as two certificates of character, of practical midwifery, and of attendance on a clinical hospital which receives cases of fever. Candidates whose case is met by Section 4 must produce, in addition to the certificates required from candidates for the licence, a certificate from the licensing medical authority to the effect that such previous professional examination has been successfully passed.

Registered practitioners of five years' standing are admitted to examination for the licence in medicine on producing certificate of registration, with satisfactory reference, and are exempted from the examination by printed questions.

Candidates who have passed the examinations for the licence in medicine must attend at the College on the Friday following, to subscribe the declaration, and to sign the roll of licentiates in medicine.

Unsuccessful candidates may be admitted to re-examination after not less than two months.

*Licence in Midwifery.*—Candidates for the licence in midwifery, who are not licentiates in medicine, may be admitted to examination on the following qualifications: (1) The degree or licence in medicine or surgery from any University or College of Physicians or Surgeons in the United Kingdom; (2) Testimonials as to character; (3) Certificates of having attended (a) a course of lectures on midwifery in a school recognised by the College; (b) practical midwifery and diseases of women, as in Section 6 of the regulations for the Licence in Medicine.

Candidates who are licentiates in medicine of the College, or who have passed the examination for such licence, may be admitted to examination for the licence in midwifery on lodging their fees and signifying their wish to the registrar a week at least before such examination.

The fees are: For the licence to practise medicine, £15 15s. Examination for the midwifery licence, £3 3s. For the licences in medicine and midwifery, if obtained within a month, to be lodged in one sum,<sup>27</sup> £16 16s. In case the candidate be a graduate both in Arts and in Medicine of any university in Great Britain or Ireland, the fee for the licence in medicine shall be £5 5s. Special examination for the licence to practise medicine, £21; for the licence to practise midwifery, £5 5s. The admission fee, less the sum paid to the examiners, is returned to any candidate rejected at any of the College examinations.

*The Membership.*—Members of the College alone are eligible to the Fellowship. Every candidate for the membership is required to produce satisfactory evidence—1. Of having attained the age of twenty-five years. 2. Of being a licentiate of this College for three years at least; or a licentiate of one year's standing, who shall be a graduate of Arts of a university in the United Kingdom at the time of his obtaining the licence; or a licentiate of one year's standing, who shall be a registered practitioner of seven years' standing at the time of his obtaining the licence. 3. Of professional conduct and moral character, as testified by a fellow or member of the College, or by a fellow of the Royal College of Physicians of London or of Edinburgh. 4. Of

<sup>26</sup> Candidates who commenced their hospital studies between September, 1878, and October, 1879, will be required to conform to Rule 4, or to produce evidence of having attended for nine months a hospital which contained fever wards.

<sup>27</sup> Any candidate rejected at the Examination for the Licence in Medicine must pay the full fee of £3 3s. for the Licence in Midwifery.

not being engaged in trade; of not directly or indirectly vending medicines or drugs; of not dispensing or compounding medicines for anyone—even his own private patients—(except in cases of extreme urgency); and of not practising medicine or surgery in partnership, by deed or otherwise. 5. Of having attended courses of practical instruction in Ophthalmology and Histology. 6. Of having held, during at least six months, the office of resident physician, or resident medical pupil, in a hospital recognised by the College; or of having acted for the same period as clinical clerk in the medical wards of such hospital; or of having been in medical charge, for at least twelve months, of any public institution for the treatment of the sick. 7. Of having lodged the admission fee of twenty guineas in the Royal Bank of Ireland to the credit of the College.

Every candidate shall be required to pass an examination in (1) Principles of Medicine, including Pathology, Medical Anatomy, and Medical Chemistry. (2) Practice of Medicine, including Principles of Public Health. (3) Clinical Medicine.

The election for fellowship takes place twice a year, on the first Friday in April, and on St. Luke's day (Oct. 18th). Candidates must be proposed and nominated three months previously. Fee, £60.

#### ROYAL COLLEGE OF SURGEONS IN IRELAND.

Students beginning their studies after May 1st, 1882, and who wish to be candidates for the Letters Testimonial of the College shall produce evidence—(a) Of having, before entering on medical studies, passed the Preliminary Examination of the College, or an equivalent examination, recognised by the General Medical Council; and (b) of having been registered by that Council as a student in medicine.

The Letters Testimonial of the College shall not be granted to any candidate at an earlier period than forty-five months subsequent to his registration as a medical student; or to anyone who has not attained the age of twenty-one.

Students may be registered as pupils of the College on payment of a registration fee of £5 5s., for which credit will be given subsequently in his examination fee.

**Examinations.**—Every candidate shall be required to pass a Preliminary Examination and four Professional Examinations, unless he possess a diploma or degree in either medicine or surgery recognised by this College, or who have passed an equivalent examination.

**Professional Examinations.**—The first, second, and third Professional Examinations shall be held in the July and October of each year; should the student fail to pass in July, he may present himself at the Examination held in October. The Examination of each year must be passed before a new session can be entered on.

**First Professional Examination.**—Candidates must have been engaged in study for at least nine months subsequent to registration. The examination shall include the following: (1) Physics, if not passed at the Preliminary Examination; (2) the Elements of Chemistry; (3) Elementary Botany; (4) Human Osteology; (5) Elementary Practical Pharmacy.

The fee for this examination shall be £5 5s.

The examination shall occupy two days. The first day printed questions and the second oral.

**Second Professional Examination.**—Candidates are required to produce evidence of having passed the first professional examination, also certificates of having subsequently attended—Medico-Chirurgical Hospital, nine months. Winter courses: Practical Anatomy, Physiology, Surgery, Chemistry (unless attended in first year). Summer courses, three months: Practical Chemistry, Practical Physiology, Materia Medica. The fee for this examination shall be £5 5s.

Candidates shall be examined in—(1) Anatomy; (2) Histology; (3) Surgery; (4) Chemistry; and (5) Materia Medica. The examination shall occupy two days—the first day (oral) in Chemistry and Materia Medica, Anatomy, Physiology, Surgery; the second day, Dissections and Histology.

**Third Professional Examination.**—Candidates must produce evidence of having passed the Second Examination, also certificates of having subsequently attended—Medico-Chirurgical Hospital, nine months as an extern pupil, or six months as a resident pupil. Winter courses: Demonstrations and Dissections, Practical Anatomy (unless attended in the first year), Surgery, and Medicine. Summer course, three months: Medical Jurisprudence.

The fee for this examination shall be £5 5s. Candidates shall be examined in—(1) Anatomy; (2) Physiology; (3) Surgery. The examination shall occupy three days. The first

day, printed questions; second, oral; and the third, dissections.

**Fourth, and Final Professional Examination.**—Shall be held in July and October, and in the following April. Candidates must produce evidence of having passed the Third Professional Examination, also certificates of having subsequently attended—Medico-Chirurgical Hospital, nine months as Extern Pupil. Winter courses: Dissections, Demonstrations, and Midwifery. Certificates will also be required of having attended a midwifery hospital, or maternity, for six months, and of having been present at thirty labours. Clinical Ophthalmology, three months. Operative Surgery. Practical Instruction in Vaccination.

The fee for this examination shall be £5 5s. Candidates shall be examined in—1. Surgery: Clinical, Ophthalmic, and Operative, with Surgical Anatomy. 2. Medicine. 3. Midwifery and Diseases of Women. 4. Medical Jurisprudence. The examination shall occupy four days. The first day printed questions; the second, oral; the third, clinical; and the fourth, operative surgery.

**Fellowship Examination for Candidates possessing no Qualification.**—The Examination shall consist of two divisions, and extend over, at least, three days; the first two of which shall be devoted to the Examination for the Letters Testimonial of the College. The third day shall be devoted to additional subjects required for the Fellowship. Candidates who do not pass the first two days' Examination shall not be allowed to proceed to the third, but those who do pass shall be entitled to receive the Letters Testimonial of the College, although they may not have passed the third day's Examination. No credit will be given, on a subsequent occasion, for passing a part only of either Examination.

#### THE SOCIETY OF APOTHECARIES, LONDON.

Every candidate for a Certificate of Qualification to practise as an Apothecary will be required to produce testimonials—Of having passed a Preliminary Examination in Arts as a test of general education. (This examination must be passed before the commencement of medical studies. Medical studies commenced before the candidates shall have passed an examination on the subject of general education will not be recognised.) Of having attained the full age of twenty-one years. Of good moral conduct. A certificate of three months' Practical Pharmacy from some recognised hospital or dispensary, or from a qualified medical practitioner. And of having pursued a course of medical study in conformity with the regulations of the court.

The course of medical study required for a licence must occupy at least four years, of which not less than three winter and two summer sessions must be passed at a recognised school or hospital. The following will be recognised and considered equivalent to eighteen months' study, in addition to the two years and a half above mentioned: (a) attendance on the practice of a hospital or other public institution recognised by this Hall for that purpose; (b) instruction as the pupil or assistant of a registered practitioner, physician or surgeon to a hospital, general dispensary, or union workhouse, or where such opportunities of practical instruction are afforded as may be deemed satisfactory.

**Course of Study.**—Every candidate must attend the following lectures and medical practice: each winter session to consist of not less than six months, to commence on the 1st and not later than the 15th October; each summer session to commence on the 1st and not later than the 15th of May.

**First Year.**—Winter Session: Chemistry, Anatomy, and Physiology (including Dissections and Demonstrations). Summer Session: Botany, Materia Medica and Therapeutics, Practical Chemistry.

**Second Year.**—Winter Session: Anatomy and Physiology (including Dissections and Demonstrations), Principles and Practice of Medicine, Clinical Medical Practice. Summer Session: Midwifery and Diseases of Women and Children, Forensic Medicine and Toxicology, Clinical Medical Practice.

**Third Year.**—Winter Session: Principles and Practice of Medicine, Clinical Medical Lectures, Morbid Anatomy, Pathology, and Clinical Medical Practice. Summer Session: Practical Midwifery and Vaccination, Morbid Anatomy, Clinical Medical Practice.

<sup>28</sup> It is proposed to omit the Principles and Practice of Medicine in the second and third winter session. One course of the Principles and Practice of Medicine is required, and one on the Principles of Surgery; the latter of which can be taken at any time convenient to the candidate after the second year.

No certificates of lectures or of anatomical instructions delivered in private to particular students apart from the ordinary classes of recognised public medical schools can be received by the Court of Examiners.

**Examination in Arts.**—This Examination will be held at the Hall of the Society on Thursday and Friday, Sept. 21st and 22nd, also in January, 1883. The fee for the examination is one guinea; not returnable in case of failure.

Prizes are annually offered for proficiency in the knowledge of *Materia Medica* and Pharmaceutical Chemistry.

**Professional Examinations.**—The Court of Examiners meet in the Hall every Wednesday and Thursday, where candidates are required to attend at 4.30 P.M. Every candidate intending to offer himself for examination must give seven days' notice previous to the day of examination. Rejected candidates cannot be re-examined until after the expiration of six calendar months.

The examination of candidates is divided into two parts, and is conducted partly in writing and partly *visu voce*.

The First Examination, which may be passed after the second winter session, embraces the following subjects:—Physicians' Prescriptions and Pharmacy; Anatomy and Physiology; General and Practical Chemistry; *Materia Medica* and Botany; Histology.

The Second Examination, at the termination of the medical studies, embraces Principles and Practice of Medicine; Pathology and Therapeutics; Midwifery, including the Diseases of Women and Children; Forensic Medicine and Toxicology; Microscopical Pathology.

Candidates are required of candidates for the Second or Pass Examination, of having completed four years' medical study, including the period spent at the hospital; of being twenty-one years of age, and of good moral conduct. Of having passed the First Examination. Of having completed the prescribed curriculum of study according to the schedule, including a personal attendance of twenty cases of midwifery; and of having received instruction in Practical Vaccination, and vaccinated not less than twenty cases. Of having served the office of clinical clerk at a recognised hospital during the period of six weeks at least. Of having been examined at the class examinations instituted by the various lecturers and professors of their respective medical schools and colleges.

**Modified Examination.**—Graduates in Medicine of British Universities will be admitted to a Clinical and Practical Examination in the Practice of Medicine, Pathology, and Midwifery.

**Fees.**—For a Certificate of Qualification to practise, six guineas, half of which is retained in case of rejection, to be accounted for at a subsequent examination. For the First Examination, three guineas, which sum is retained in case of rejection and accounted for subsequently. For the Second Examination, three guineas. For an Assistant's Certificate two guineas, which sum is retained in case of rejection and accounted for subsequently.

#### APOTHECARIES' HALL OF IRELAND.

The *Arts Examination* will be held at the Hall four times in the year—viz., the third Thursday in January, April, July, and October, at 11 A.M.

**Professional Education.**—Every candidate for the licence to practise Medicine and Pharmacy must produce certificates to the following effect:—Of having passed an examination in Arts previously to entering on professional study. Of registration as a medical student from the Registrar of the Medical Council. Of being at least twenty-one years of age, and of good moral character. Of pupilage to a qualified apothecary, or of having been otherwise engaged at *practical Pharmacy* for a period of twelve months subsequent to having passed the examination in Arts. Of having spent four years in professional study. Of having attended the following courses—namely: Chemistry, during one winter session; Anatomy and Physiology, during one winter session; Demonstrations and Dissections, during two winter sessions; Botany and Natural History during one summer session; Practical Chemistry (by daily instruction in a recognised laboratory), during three months; *Materia Medica* during three months; Principles and Practice of Medicine during one winter session; Pathology, a course; Midwifery and Diseases of Women and Children, during six months; Practical Midwifery at a recognised hospital (attendance upon twenty cases); Surgery, during one

winter session; Forensic Medicine, during one summer session; instruction in the practice of Vaccination. Of having attended at a recognised hospital or hospitals the practice of Medicine and Clinical Lectures on Medicine, during two winter and two summer sessions; also the Practice of Surgery and Clinical Lectures on Surgery, during one winter and one summer session. Of practical study, with care of patients, as apprentice, pupil, assistant, clinical clerk, or dresser. Of having performed Vaccination successfully under a vaccinator recognised by the Local Government Board.

The *Examination for the Licence* is divided into two parts. The first part comprehends Chemistry, including Physics, Botany, Anatomy, Physiology, *Materia Medica*, and Pharmacy; the second, Medicine, Surgery, Pathology, Therapeutics, Midwifery, Forensic Medicine, and Hygiene.

Candidates at the examination on Anatomy are liable to be called on to perform dissection; and at the examination on Surgery to perform operations on the dead subject.

The *Professional Examinations* will be held quarterly, and will commence on the first and second Monday in January, April, July, and October. They will be carried on as follows:—The first part on the first Monday at eleven o'clock A.M. and on the Tuesday and Wednesday succeeding at the same hour. Subjects: Chemistry, including Chemical Physics, and Botany, Monday; *Materia Medica* and Pharmacy, Tuesday; Anatomy and Physiology, Wednesday. The second part, or final examination, on the second Monday at eleven o'clock A.M.; and on the Tuesday and Wednesday succeeding at the same hour. Subjects: Medicine and Surgery, including Pathology and Therapeutics, Monday; Midwifery and Diseases of Women and Children, Tuesday; Forensic Medicine and Hygiene, Wednesday; Clinical Examination, Thursday.

#### THE ARMY, NAVY, AND INDIAN MEDICAL SERVICES.

Admission into the Army and Indian Medical Services is gained as the result of competitive examination; for although by the last Army Warrant power is reserved to the Secretary of State for War to fill up, without an examination, a number not exceeding half the vacancies in the department, with qualified candidates recommended by the governing bodies of public schools of medicine in the United Kingdom or Colonies, this has never yet been exercised. Candidates for both services must, before being admitted to examination, possess the double qualification to practise medicine and surgery, and be registered under the Medical Act, and must also furnish satisfactory certificates of moral character. Candidates for the army must be between the ages of twenty-one and twenty-eight, in good health, and both parents of unmixed European blood; for the Indian service, between twenty-two and twenty-eight, of sound bodily health, and natural born subjects of Her Majesty. Both are examined as to physical fitness by a Board of Medical Officers. These conditions being satisfied, the candidate is admitted to the competitive examination, which is usually held in London twice a year, in the months of February and August. The number of appointments to be competed for on each occasion varies according to the requirements of the services. The subjects of examination are divided into *compulsory* and *voluntary*. The former comprise Anatomy and Physiology, Surgery, Medicine, including Therapeutics and the Diseases of Women and Children, Chemistry and Pharmacy, and a practical knowledge of Drugs. The eligibility of the candidate for admission into the service is determined by the result of this part of the examination. The *voluntary* subjects are French, German, Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany, with special reference to *Materia Medica*, and for the Indian service Hindustani. Although the results of the examination on voluntary subjects do not affect the question of the eligibility of the candidate for a commission they influence his position on the lists, which is determined by the numbers obtained under the two heads conjointly. After having passed this examination the successful candidates for both services are sent to the Army Medical School at Netley as "surgeons on probation," with the rank of lieutenant and the daily pay of 8s., to go through a four months' course of special instruction in the duties required of them in the service. The staff of the school consists of four professors, all of them men of acknowledged ability and high

standing in their special departments; Surgeon-General Longmore, C.B., is Professor of Military Surgery; Inspector-General Maclean, M.D., C.B., of Military Medicine; Surgeon-Major de Chaumont, M.D., F.R.S., of Military Hygiene; and Dr. Aitken, F.R.S., of Pathology. To each of these an Army Medical Officer is attached as Assistant Professor. The lectures on Military Surgery include gunshot and other wounds, transport of sick and wounded, duties of army medical officers in the field, during sieges, and on board troopships and transports, &c. Those on Military Medicine treat of tropical and other diseases to which soldiers are exposed in the course of their service, the mortality and invaliding by disease, in peace and war, at home and abroad. The course of Hygiene comprises the examination of water and air, the general principles of diet, with the quality and adulterations of food and beverages, the sanitary requirements of barracks, hospitals, and camps, the clothing, duties, and exercises of the soldier, and the circumstances affecting his health, with the best means of preventing disease, and instruction in the mode of preparing the various statistical and other returns required of the medical officer. The lectures on Pathology are chiefly directed to morbid anatomy and the results of tropical diseases, with practical instruction in the microscopic examination of morbid tissues. The surgeons on probation are detailed for duty in the wards of the hospital, under the Professors and Assistant-Professors of Medicine and Surgery, and receive practical instruction in the mode of examining recruits. The Surgeons on probation are provided with quarters and are members of the excellent mess established at Netley. After having passed through the course of instruction they are examined on the subjects taught in the school. For the army this is merely a "pass," and does not affect the position gained at the entrant examination; for the Indian service the numbers obtained are added to those previously assigned, and the seniority on the list is determined by the combined results of the preliminary and final examinations. At the close of each session five prizes are awarded: the Herbert prize of £20 to the surgeon on probation who has obtained the highest number of marks at the London and Netley examinations conjointly; the Parkes Memorial Bronze Medal to the one who gains the highest number of marks in the examination on Hygiene at Netley, combined with those given for the answers to a special question set on the same subject; the Martin Memorial Gold Medal to the highest number of marks in the final examination on Military Medicine, with the addition of those gained for a special question connected with it; the Montefiore Gold Medal and £20, awarded in the same manner for Military Surgery; and the Montefiore second prize, consisting of works on Military Surgery, to the surgeon on probation who obtains the second highest numbers in this branch. The competition for the last four prizes is optional.

The conditions of admission into the Naval Medical service are the same as those for the Army; but the candidate is also required to declare his readiness to engage for general service and to proceed on duty abroad whenever required to do so. After having passed the competitive examination in London the successful candidate will receive a commission as surgeon in the Royal Navy, "and will undergo a course of practical instruction in Naval Hygiene at Haslar Hospital." At present Fleet Surgeon Walter Reid, M.D., has been appointed to Haslar "for instruction of surgeons on entry," and Surgeon H. B. Collins "to assist in instruction of surgeons on entry;" but we have no information as to the length of the course, the conditions under which it is conducted, or the subjects professed to be taught.

The following tables, showing the rates of pay and half-pay of the three branches, will probably be acceptable to students who entertain any intention of entering the public service.

## ARMY.

Rank.	Rates of Pay.	Gratuities.	Relative Military Rank.
	Daily.		
Surgeon on probation ..	£0 8 0 ..	—	Lieutenant
	Annual.		
Surgeon ..	200 0 0 ..	—	Captain
" aft. 5 years' service	250 0 0 ..	—	
	Daily.	Gratuity.	
" 10 ..	0 15 0 ..	£1250 ..	
Surgeon-Major ..	1 0 0 ..	—	Major
" aft. 15 years' service	1 2 6 ..	£1800 ..	
" 18 ..	—	£2500 ..	

Rank.	Rates of Pay.	Half-pay.	Relative Military Rank.
Surgeon-Major:			
" aft. 20 years' service	1 5 0 ..	£1 0 0 ..	Lieut.-Colonel
" 25 ..	1 7 6 ..	1 2 6 ..	
" 30 ..	—	1 5 0 ..	
Brigade-Surgeon ..	1 10 0 ..	—	Lieut.-Colonel
" aft. 5 years in rank	1 13 0 ..	—	(but always senior to)
" aft. 20 years' service	—	1 7 6 ..	Surgeon-Major)

Surgeons are promoted to Staff Surgeons after twelve years' service, provided they pass the requisite examination, and Staff Surgeons to Fleet Surgeons after twenty years, if recommended by the Director-General. Deputy Inspectors-General are promoted by selection from the Fleet Surgeons, and Inspectors-General from the Deputy Inspectors-General having three years' foreign, four years' mixed, or five years' home service. Inspectors and Deputy Inspectors-General are retired compulsorily at sixty, and other grades at fifty-five years of age, and all ranks at any time if they have not served for five years. In calculating service for retired pay, time on half-pay will be taken as equivalent to one-third service on full-pay.

## METROPOLITAN HOSPITALS AND MEDICAL SCHOOLS.

**ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.**—The clinical practice of the hospital comprises a service of 710 beds, of which 676 are in the hospital at Smithfield, and 34 are for convalescent patients at Lauderdale House, Highgate.

Four house-physicians, ten house-surgeons, and a midwifery assistant are appointed annually, each of them holding office for one year, and provided with rooms by the hospital authorities. The ophthalmic house-surgeon is appointed for six months, and is eligible for re-election for a second term of six months. The senior assistant chloroformist and junior assistant chloroformist are appointed annually, and are provided with rooms. No fee is paid for any of these appointments, and each receives a salary of £25. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical out-patients, and the dressers in the special departments are chosen from the diligent students. Forty ward-dresserships are given annually to the students who pass the best examination in the subjects of study of the first year. Other ward-dresserships may be obtained by payment of the usual fees.

A college is attached to the hospital, in which students can reside, subject to the college regulations.

**Foundation and other Prizes.**—Open Scholarships in Science of the value of £120 each, tenable for one year, will be competed for September 25th. Candidates must not be more than twenty-five years of age for one, and twenty-one for the other, and must not have entered to the medical or surgical practice of any metropolitan medical school. The subjects of examination are Physics, Chemistry, Botany, Physiology (not more than four subjects to be taken), and Zoology.—Preliminary Scientific Exhibition (founded 1873). The subjects of examination are identical with those of the Open Scholarship in Science. This Exhibition, of the value of £50, is tenable for one year. The examination is confined to students of the Hospital of less than six months' standing, and will be held October 28th. The Jeaffreson Exhibition, of the value of £50, and tenable for two years, is awarded after examination, beginning September 25th, in the subjects of General Education. It is now an Open Exhibition. A Senior Scholarship, £50, in Anatomy, Physiology, and Chemistry. Lawrence Scholarship, and Gold Medal, of the value of forty guineas (founded in 1873 by the family of the late Sir Wm. Lawrence). Two Brackenbury Scholarships in Medicine and Surgery, £30 each. Junior Scholarships in the subjects of study of the first year: 1st, £50; 2nd, £30; 3rd, £20.

**CHARING-CROSS HOSPITAL AND COLLEGE.**—The fee for matriculation, which involves no examination, is £2 2s., to be paid on entering. Matriculated students pay proportionately lower fees, and are admitted without additional fee to the courses of Clinical Medicine and Surgery, the lectures on Psychological Medicine, and to the practice of the Royal Westminster Ophthalmic Hospital. They alone are entitled to compete for the scholarships, gold medal, and Pereira prize.

Two Entrance Scholarships, of the value of £30 and £20 respectively, tenable for one year, are awarded annually in October, after a competitive examination in the following subjects:—*Compulsory*, English, Latin, French or German, Mathematics; *Optional* (only one of which may be selected), Chemistry, Mechanics, German or French, the subjects being those of the matriculation examination of the University of London. Candidates must give notice of their intention to compete on or before Saturday, Sept. 21st, 1882. Two scholarships are open for competition among the matriculated students: the Llewellyn Scholarship of £25, for students who have just completed their second year; and the Golding Scholarship of £15, for students who have just completed their first year. The Pereira Prize of £5 is open to all matriculated students, and is awarded annually for the best clinical reports.

The various resident appointments are open to all matriculated students without additional fee.

**ST. GEORGE'S HOSPITAL.**—Perpetual pupils, by payment of £130 in three instalments, or £125 in one sum, are entitled to admission to the medical and surgical practice;

to compete for prizes and exhibitions; to hold the appointments of house-physician and house-surgeon, assistant house-physician, assistant house-surgeon, ophthalmic assistant, and to become clinical clerks for two periods of three months each, and dressers for similar periods. The house-physician and house-surgeon receive their board and lodging free, and no payment is made for the appointment. Gentlemen are admitted to the hospital practice and lectures required by the College of Physicians and Surgeons and the Society of Apothecaries on payment of £45 at the commencement of the first year of study, £45 at the commencement of the second year of study, £20 for the third, and £20 for the fourth year. These payments entitle the pupil to hold the offices of clinical clerk and dresser for three months each, and to become a candidate for the offices of medical and surgical registrar and demonstrator of anatomy and curator of the museum. There are all salaried offices. The obstetric assistant is resident, with a salary of £100.

**Prizes.**—The William Brown Exhibition of £100 per annum, tenable for two years, open to any perpetual pupil of St. George's who is under twenty-five years of age, and who shall have obtained a diploma or licence entitling him to be registered as a practitioner of medicine or surgery in England, within two years previous to the period fixed for the examination (July). The examination is to test the proficiency of the candidate in Medicine, Midwifery, and Surgery, including Ophthalmic Surgery. The William Brown Exhibition of £40 per annum, tenable for three years, for general fitness for the exercise of the medical profession, and for moral conduct, open to perpetual pupils in their fourth year of study. Sir Charles Clarke's Prize (interest of £200 Consols) for good conduct. The Brackenbury Prize in Medicine, value nearly £40; the Brackenbury Prize in Surgery, value nearly £40; open to all pupils of the hospital.

**GUY'S HOSPITAL.**—House-physicians and house-surgeons, obstetric residents, dressers, clinical and other clerks, are selected from the students, according to merit, and without payment. The house-physicians, of whom there are three constantly on duty, one as junior and two as seniors, hold office for six months each, the first two months in the former capacity, the other four in the latter. The duty of the junior house-physician is to attend in the medical out-patient room three times a week, in a room adjoining that occupied by the assistant-physician for the day, and prescribe for those patients who are not seen by the assistant-physician. The senior house-physicians are chiefly occupied in the medical wards, and attend to all emergencies that may arise in the absence of the physicians. They have separate rooms in the clinical building, and are boarded at the charge of the hospital. The house-surgeons, of whom there are also three on duty, hold office for six months each. During the first two months the house-surgeon assists in the out-patient department. During the next two months he has the general superintendence of the surgical casualty department, and assists the senior when required; and subsequently, as senior house-surgeon, he has, in the absence of the surgeons and assistant-surgeons, the care of the patients in the surgical wards, and lives during these four months in the hospital, being boarded free of expense. The dressers are selected from those gentlemen who have completed their third winter session, and who have been most diligent in the junior appointments. They hold office for six months each. Three are attached to each surgeon. During their week of special duty they reside in the hospital, and board with the house-surgeons free of expense. Two obstetric residents reside, and are boarded in the hospital.

**Scholarships, Prizes, &c.**—Open Scholarship of the value of £131 5s. in Arts, Latin, Greek, Mathematics, and modern languages. Open Scholarship of £131 5s. in Science. Subjects: Inorganic Chemistry, Zoology, Botany, Physics (these will be competed for on Monday, September 25th). At the end of the summer session: first prize, £50; second prize, £25. Subjects: Anatomy, Physiology, Chemistry, Materia Medica, and Botany or Comparative Anatomy.—For Students in their second year: First prize, £25; second prize, £10. Subjects: Anatomy, Physiology. The Sands Cox Scholarship of £15 per annum for three years. Subject: Physiology. The Michael Harris Prize of £10 for Anatomy.—For Students in their third year: First prize, £25; second prize, £10. Subjects: Medical and Surgical Anatomy, Midwifery and Therapeutics. Fourth year's Students: First prize, £25; second prize, £10. Subjects: Medicine, Surgery, Midwifery, and Medical Jurisprudence.—

For Senior Students: The Treasurer's Gold Medal in Medicine; the Treasurer's Gold Medal in Surgery; the Gurney Hoare Prize of £25, for Clinical Medicine and Surgery. The Beane Scholarship, of thirty guineas, for Pathology. The Physical Society awards the following prizes: Two of £5 each to the members who send in the best essays on selected subjects; prizes of £10 and £5 for the best papers read before the Society; and one of £5 to the member who has most distinguished himself in the debates of the sessions.

The Library is supplied with weekly, monthly, and quarterly journals of medicine, natural history, and philosophy. It is open to the students from 9.30 A.M. to 5.30 P.M.

**KING'S COLLEGE.**—The physicians' assistants, the physician-accoucheur's assistant, the clinical clerks, and the house-surgeon and dressers are selected by examination from among those matriculated students of the college who are pupils of the hospital. The College and Hospital fees amount to £125 if paid in one sum on entrance, to £130 if paid in two instalments—viz., £70 on entrance and £60 at the beginning of the second winter session; or to £135 if paid in three instalments—viz., £60 on entrance, £50 at the beginning of the second winter session, and £25 at the beginning of the third. Students are recommended to add to the above the fee for attendance on the Medical Tutors' class for one year—namely, £3 3s. for the first year's subjects, or in the case of those preparing for the Preliminary Scientific Examination of the University of London, £5 5s. All resident students are required to attend the tutor during their first year. Rooms are provided within the walls of the college for the residence of a limited number of matriculated students. Registration fee at hospital 10s. 6d. Rooms and commons are provided at the hospital for the resident officers free of charge.

**Scholarships.**—Warneford Scholarships: Two of £25 per annum for three years. Science: One of £50 and one of £25 each for two years. Sambrooke: One of £60 and one of £40 for Science and Literature. College Scholarships: One of £40 per annum, for two years; one of £30, for one year; three of £20 for one year. The Daniell Scholarship of the annual value of £20. Sambrooke Registrarships, of the annual value of £50 each, and tenable for two years, are open to all matriculated students who have filled any one of the higher appointments of the hospital, or who have become Associates. The Leathes Prizes, value £7, and the Warneford Prizes, value £40, are given annually amongst the matriculated medical students. Two Medical Clinical Prizes, one of £3 for the winter session, and one of £2 for the summer session, and two Surgical Clinical Prizes, of £3 each, are given. The Todd Medical Clinical Prize consists of a bronze medal and books to the value of £4 4s. The Tanner Prize for Obstetric Medicine, value £10, and the Carter Gold Medal and Prize for Botany, value £15, are given annually in July. All students, occasional as well as matriculated, are admitted to contend for the class prizes.

**LONDON HOSPITAL AND COLLEGE.**—The Medical School of the London Hospital is under the direction of a College board, composed of six members of the hospital staff, and six of the house committee. The executive authority is committed to a Warden. The hospital, which is the largest in Great Britain, contains nearly 800 beds. Last year the number of in-patients was 6840; out-patients 58,307.

The following Scholarships and Prizes will be offered for competition during the ensuing winter and summer sessions:—Two Entrance Scholarships in Natural Science, of the value of £60 and £40 respectively, will be offered for competition on September 25th, 26th, and 27th, 1882. The subjects are Physics, Botany, Zoology, and Inorganic Chemistry. The successful candidates must forthwith become full pupils of the hospital and school, if not already entered; and are not eligible to compete for the Buxton Scholarships:—The Two Buxton Scholarships, value £30 and £20, will be offered for competition on September 28th, 29th, and 30th, 1882. The subjects are those appointed by the General Council of Medical Education and Registration as the subjects of the Preliminary Examination. A Scholarship, value £25, in Anatomy, Physiology, and Chemistry, will be competed for at the end of the winter session, by first and second year students. The Letheby Prize, value £30, for proficiency in Chemistry. (At the end of the sum-

mer session.) Open to all full students who have completed their second summer session up to the termination of their fourth year from entrance. A Hospital Scholarship, value £20, for proficiency and zeal in Clinical Medicine. (At the end of the winter session.) A Hospital Scholarship, value £20, for proficiency and zeal in Clinical Surgery. (At the end of the winter session.) A Hospital Scholarship, value £20, for proficiency and zeal in Clinical Obstetrics. (At the end of June.) The Duckworth Nelson Prize, value £10, will be offered biennially for competition at the end of the winter session, and be open to all students on similar conditions to those of the Hospital Scholarships. The subjects of examination will be Practical Medicine and Surgery. Out-Patients Dressers' Prizes. Six prizes of the aggregate value of £60 will be offered for competition at the end of the winter session. Candidates must pass an examination in Minor Surgery, must have dressed diligently for twelve months, and have passed the Primary Examination of the Royal College of Surgeons. Special certificates are given to those gentlemen who have faithfully performed their duties in the hospital, and to those who have distinguished themselves at the examinations for scholarships and prizes.

**Appointments.**—The resident appointments consist of five house-physicians, five house-surgeons, and one accoucheurship. Two dressers and two maternity pupils also reside in the hospital. (N.B.—The holders of all the resident offices are provided with rooms and board free of expense.) There are also three clinical assistants in the out-patient departments, at a salary of £80 each. Medical registrar, salary £100. Surgical registrar, salary £100. There are also numerous appointments for clinical clerks, dressers, maternity pupils, post-mortem clerks, &c., without additional fees. Special classes for the Preliminary Scientific and other examinations are held throughout the year.

For instruction in Mental Diseases, students can attend, without further fee, the practice of Dr. John Millar, medical superintendent of Bethnal House Asylum, a few minutes' walk from the hospital.

Students who have passed the Preliminary Scientific Examination at the University of London, and have obtained signatures for Lectures on Botany, Zoology, Chemistry, and Practical Chemistry, shall have the fees for the same, amounting to £18 18s., remitted on entering as full students at the London Hospital; and students who have attended the above courses elsewhere, and have obtained signatures for the same previous to their entrance at the London Hospital, shall also have these fees remitted, provided they pass the Preliminary Scientific Examination within eighteen months of their entry as full students.

General fee to lectures and hospital practice, 90 guineas, in one sum, or 100 guineas payable in three instalments of 45, 40, and 15 guineas at the commencement of the first, second, and third years respectively. Special entries can be made to lectures or practice.

For the convenience of gentlemen attending the Hospital and College, a Student's Club has been erected in the hospital grounds, where refreshments can be obtained at moderate charges.

**ST. MARY'S HOSPITAL.**—There are four resident medical officers, three of whom are appointed for twelve months, and one, the obstetric officer, for six months, who board free of expense in the hospital. These appointments are awarded after competition, without additional fee. There is also a resident dresser. A resident registrar is appointed from amongst the students, with a salary of £100 a year and dispensary fees, who resides free of expense in the hospital. In addition to the above, two demonstrators of anatomy are appointed annually with a salary; and the medical tutor in like manner, with a salary of £100 a year. All these officers are eligible for re-election.

All general students are required to perform the duties of clinical clerk and dresser during the last two years of their curriculum. Students of the third year and of subsequent years are also appointed to assist the physicians and surgeons in charge of the out-patients. There is a Hospital Medical Society, which meets regularly during the winter session.

A Maternity Department is attached to the hospital. There are special departments for Diseases of the Eye, the Ear, the Skin, and the Throat, in which clinical demonstrations are constantly given by the physicians and surgeons.

**Scholarships, Prizes, &c.**—Three Scholarships in Natural Science, each tenable for three years, and of the value of £60 the first year, £40 the second, and £20 the third year,

and an Exhibition in Natural Science of the value of £20, tenable for one year. One of the Scholarships and the exhibition are awarded, immediately before the commencement of each winter session, by open competitive examination. An extra Scholarship in Natural Science, tenable for three years, of the value of £60 the first year, £25 the second, and £15 the third, will also be awarded by open competition in October, 1882. A Scholarship in Anatomy of the annual value of £20, for students who have completed their second winter session; and a Scholarship in Pathology of £20, for students who have completed their third winter session. Examinations will be held and prizes awarded in the various classes of each year, at the termination of both the summer and winter sessions. Two prosectors are annually appointed, who each receive £5 and a certificate for their services.

Fee to the hospital practice and lectures, 107 guineas in instalments, or 101 guineas in one sum; perpetual, 125 guineas in instalments, or 119 guineas in one sum. Fee to the hospital practice and lectures required for the examination in Dental Surgery by the College of Surgeons, 62½ guineas. Special entries can be made to courses of lectures or periods of hospital practice; no fee for registration.

Practitioners in the neighbourhood receive pupils to reside with them; information on this point may be obtained from the Dean.

**MIDDLESEX HOSPITAL.**—There is a special Cancer Department, affording accommodation for thirty-three in-patients, whose period of residence in the hospital is unlimited. Classes, open to all the students, are held for practical instruction in the microscopical examination of healthy and diseased tissues, and also in the application of bandages and other surgical apparatus. Students are allowed to take out to read at their own homes the books from the large and carefully selected medical library of the school. Two Entrance Scholarships, of the annual value of £25 and £20, and tenable for two years, also a Science Scholarship, value £50, are offered for competition at the commencement of the winter session. An Exhibition in Elementary Anatomy, Osteology, and Physiology, value £10 10s., is awarded to students at the end of their first year. Two Broderip Scholarships, of the annual value of £30 and £20, tenable for two years, are awarded to those students who pass the best examination at the bedside and the post-mortem room. The Murray Medal and Scholarship, founded in connexion with the University of Aberdeen, is awarded every third year to a student of this hospital; it will be next awarded in May, 1883. The Governors' Prize of twenty guineas is also awarded annually to the student who shall most distinguish himself during his three years' curriculum. Valuable class prizes are also given, and ten resident clinical appointments are annually awarded, after competitive examination, to students who have completed their education, and complied with the regulations of the school. The officers thus appointed reside and board in the hospital free of expense. The college tutor assists all general students, especially those who are preparing for examination, free of charge; and his instruction is arranged with a view to avoid the necessity of students obtaining any private tuition apart from that of the Medical School. The fee for attendance on the hospital practice and lectures required by the Colleges of Physicians and Surgeons and by the Society of Apothecaries is 90 guineas, if paid in one sum on entrance. The fees may be paid by instalments—£40, first year; 40, second year; £20, third year; £5, fourth year.

The clinical clerk and dresser of the physician and surgeon of the week dine at the board-room table, free of charge. A limited number of general students are also allowed to dine at the board-room table. The paid offices of medical registrar, surgical registrar, resident medical officer, and demonstrator of anatomy are open to qualified men as they become vacant. All clinical clerkships and dresserships are awarded without fee.

**ST. THOMAS'S HOSPITAL.**—*Prizes and Appointments for the year 1882-3.*—For First-year's students: Two Entrance Scholarships in Natural Science of the value of £100 and £60 respectively, open to all first-year's students, will be awarded during the first week in October, after an examination in Physics, Chemistry, and either Botany or Zoology at the option of the candidate; the William Tite Scholarship, the proceeds of £1000 Consols (£30 per annum), is awarded each year; also prizes of £20 and £10; summer, £15 and £10. For Second-year's Students: The College Scholarship of

40 guineas, and the Musgrove Scholarship of 40 guineas, are awarded biennially to the student who shall take the highest place in the first-class list in the examinations at the end of the second winter session; they are tenable for two years, provided the holder obtains a place in the first class in the subsequent examinations: making the winter prizes, £42, £20, and £10; summer, £15 and £10; with the dresserships and the clinical clerkships. For Third-year's students (winter): Second Tenure of Scholarship £42, and prizes of £20, £15, and £10, and the Prosecutor's Prize of £5; summer, £15 and £10. Clinical clerks and dressers are selected according to merit. The Grainger Testimonial Prize of £20, awarded biennially to third or fourth-year's students, for the best Physiological Essay, to be illustrated by preparations and dissections; the Cheselden Medal, for Surgery and Surgical Anatomy; and the Mead Medal, for Practical Medicine, are awarded annually to fourth-year's students. The Solly Medal, with a prize from 10 to 20 guineas, will be awarded biennially to a student of the third, fourth, fifth, or sixth year, for the best report of Surgical Cases. The Treasurer's Gold Medal, for general proficiency and good conduct, is awarded annually to a fourth-year's student. The house-physicians, house-surgeons, assistant house-physicians and surgeons, and resident accoucheur are chosen from gentlemen who have obtained their professional diplomas according to merit, and, with the dressers, are provided with rooms and commons. Two hospital registrars, at £100 per annum each, will be selected from gentlemen distinguished for merit.

The medical and surgical casualty out-patients are seen by the resident assistant-physician, the resident assistant-surgeon, the house-physicians, house-surgeons, and dressers, at from 12 to 1 o'clock daily. The Dissecting-room is open to the students from 9 A.M. to 5 P.M.

The fee to hospital practice and lectures may be paid in several ways:—1st. £125, paid on entrance. 2nd. £135, in two payments—£75 on entrance, and £60 at the beginning of next year. 3rd. Payment by three instalments—viz., of £65 at the beginning of the first year, £50 at the beginning of the second year, and £30 at the beginning of the third year entitles a student after the payment of the third instalment to an unlimited attendance. The fee for attendance on the general subjects required of students in Dental Surgery, is for the two years £55, or by instalments £50 for the first year and £10 for the second year. Regularly qualified medical practitioners are admitted to the hospital practice and to the lectures and library on payment of a fee of £12 10s. for unlimited attendance.

Special classes are held throughout the year for the Matriculation, Preliminary Scientific, and 1st M.B. examinations of the University of London.

**UNIVERSITY COLLEGE, LONDON.**—The fees for lectures and hospital practice required by the College of Physicians and Surgeons and the Society of Apothecaries during the student's entire course amount to 125 guineas if paid in one sum, or 130 guineas if paid by instalments—viz., first year 60 guineas, second year 50 guineas, third year 20 guineas.

*Exhibitions, Prizes, &c.*—Three Entrance Exhibitions, of the respective values of £100, £60, and £40 per annum, tenable for one year, are annually awarded, upon examination by printed papers, to gentlemen who are about to commence their first winter attendance in a medical school. The subjects of the examinations are—Chemistry, Physics, Botany, and Zoology. The next examination will take place at the College on September 27th and 28th. The Atkinson Morley Surgical Scholarship of £45, tenable for three years, is annually awarded to the student who, upon examination, is found to possess the greatest proficiency in the Theory and Practice of Surgery. The Sharpey Physiological Scholarship of about £105 per annum, tenable for three years, for proficiency in Biological Science. Filliter Exhibition: a prize of £30 is awarded annually, in July, to the most proficient student in the class of Pathological Anatomy. An Atchison Scholarship, value about £55 per annum, tenable for two years. The Morris Bursary of £25 a year, tenable for two years. Besides the above, gold and silver medals and other prizes are awarded in each class. The appointments of demonstrators of anatomy, of resident medical officer to the hospital, and of surgical registrar—all of which have emoluments attached to them—are almost invariably conferred upon students of the College. Physicians' assistants, house-surgeons, midwifery assistants, physicians' clerks, surgeons' dressers, ward clerks, and

ophthalmic surgeons' assistants are selected from the pupils, without additional fees.

**WESTMINSTER HOSPITAL.**—The Hospital contains upwards of 200 beds. There are separate departments for Diseases of the Eye, Ear, Skin, Teeth, and Throat, and for Diseases of Women. The Anatomical Museum is constantly open to the students. There are also a Pathological Museum and a Materia Medica Museum.

In addition to the practice of the Hospital, pupils who enter for the whole period of medical education may attend, without further fee, the practice of the Royal Westminster Ophthalmic Hospital, and of the Royal Hospital for Paralysis. Instruction in the Physical Examination of the Chest is given by Dr. Dunkin, and in the use of the Laryngoscope by Dr. Dr. Haviland Hall. Mr. R. Davy gives demonstrations in Orthopaedic subjects.

A Curator of the Museum and Pathologist with a salary of fifty guineas, and a Medical and a Surgical Registrar are appointed annually, each with a salary of £40. Two House-Physicians, a House-Surgeon, and a Resident Obstetric Assistant are appointed for six months after examination, and are provided with rooms and commons. They each pay a deposit of £20 on appointment; but receive £25 at the expiration of the term if their duties have been performed satisfactorily. An Assistant House-Surgeon is appointed from among the senior students; he is provided with commons at the hospital table. Clinical Assistants to the Physicians and Surgeons, and to the officers in charge of special departments, are appointed from students of the fourth year. Every student must perform the duties of Clinical Clerk and Dresser.

**Scholarships and Prizes.**—The Fence and Houldsworth Entrance Scholarship, each £40 a year or two years; and one Entrance Scholarship value £40. Exhibition in Anatomy, Physiology, and Chemistry, value £10 10s., tenable for one year for first year's men. A Prize of £2 2s., by Mr. A. P. Gould, to the first year's student who is most regular and diligent in the Dissecting Room. Scholarship in Anatomy and Physiology, value £21, given by His Grace the Duke of Westminster, President of the Hospital, to student of second year (to be styled Assistant Demonstrator). At the end of the third summer, Prizes of £5 each (books or instruments), in Clinical Medicine and Clinical Surgery. Frederick Bird, Medal and Prize, value £15, to students who have completed their fourth winter; subjects of examination? Medicine, Midwifery, Diseases of Women and Children, and Pathology. Chadwick Prize for General Proficiency, £21 (books or instruments), to the most meritorious student or students of any year not exceeding the fifth. In most of the classes, Special Prizes are given by the Lecturers; and Certificates of Honour are awarded in each Class. Two Tutors assist and guide the students in their work, and hold Senior and Junior Classes. Special Classes for the Preliminary Scientific M.B. examination commence in January.

**GREAT NORTHERN HOSPITAL, Caledonian-road.**—Consulting-Surgeon: Frederick Le Gros Clerk. Physicians: Drs. Cholmeley, Cook, Robert Bridges, Burnet, and Beale. Obstetric Physicians: Drs. Gustavus C. P. Murray and Fancourt Barnes. Ophthalmic Surgeon: Mr. R. W. Lyell, F.R.C.S. Surgeons: Messrs. Gav, W. Adams, W. Spencer Watson, J. Macready, and C. B. Lockwood. Aural Surgeon: Mr. A. E. Cumberbatch. Chloroformist: Mr. George Eastes. Dental Surgeon: Mr. E. Keen. House-Surgeon: Mr. J. N. Cook. Junior Resident Medical Officer: Mr. W. Brewster.

**HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.**—Consulting Physicians: D. C. J. B. Williams, F.R.S., Dr. W. H. Walshe, Dr. R. Quain, F.R.S., Dr. J. E. Pollock. Consulting Surgeon: Professor John Marshall, F.R.S. Physicians: Drs. E. S. Thompson, C. T. Williams, R. D. Powell, J. Tatham, R. E. Thompson, and F. Roberts. Assistant-Physicians: Drs. T. H. Green, J. M. Bruce, J. Fowler, P. Kidd, C. Y. Bies, and I. Owen. Pathologist: vacant. Dental Surgeon: Mr. C. J. Noble. Resident Medical Officer: Dr. F. J. Hicks. Secretary: Mr. H. Dobbin. Three clinical assistants reside in the hospital for a period of six months. Pupils are admitted to the practice of the hospital: terms, £3 3s. for three months; perpetual, £5 5s. The medical practice of the hospital is recognised by the University of London, the Apothecaries' Company, and the Army and Navy and Indian Medical

Board. The hospital contains 192 beds. 137 additional in the new extension building.

**ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.**—Established 1814. 26 beds. Consulting Physicians: Drs. Herbert Davies and Horace Dobell. Physicians: Drs. G. Goddard Rogers, P. J. Hensley, Gilbert Smith, and D. W. Finlay. Assistant-Physicians: Dr. W. Murrell, H. S. Gabbett, and W. H. White. Consulting Surgeon: Mr. Jonathan Hutchinson. Surgeon: Mr. W. J. Walsham. House-Physician: Dr. Duncan Burgess. In-patients, 269; out-patient cases, 6875. This hospital has been enlarged by the addition of a very complete new out-patients' department, and wards for 14 additional in-patients. The office of house-physician, which is tenable for six months, and for which a sum of at the rate of £30 per annum is voted in lieu of board is filled up in April and October.

**NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, 23, 24, and 25, Queen-square and Powis-place, Bloomsbury.**—120 beds; 10 cots for children. The physicians attend every Monday, Tuesday, Wednesday, and Friday, at 2.30 P.M. In- and out-patients' practice and electrical room treatment at that hour. Physicians: Drs. Ramskill, Radcliffe, Hughlings Jackson, and Buzzard. Physicians for out-patients: Drs. H. Charlton Bystian W. R. Gowers and Ferrier. Assistant-Physicians: Dr. Ormrod and Horrocks. Surgeon: W. Adams, F.R.C.S. Resident Medical Officer and Registrar: C. F. Cogwell, M.B. Cantab. Medical practitioners and students will be admitted on showing their cards.

**ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.**—The hospital, founded in 1804, and considerably enlarged in 1876, now contains 100 beds for patients, which were occupied during last year by over 1500 persons. The out-patients are yearly over 20,000. Operations are performed daily from half-past ten to one o'clock, and three surgeons attend on each day: Mr. Streetfield, Mr. Ware, Mr. Adams, on Monday and Thursday; Mr. Lawson, Mr. Cooper, and Mr. Tweedy, on Tuesday and Friday; Mr. Wordsworth, Mr. Hulke, and Mr. Lyell, on Wednesday and Saturday. Students are admitted to the practice. Fees for six months, £3 3s.; perpetual, £5 5s.; with admission to demonstrations and lectures, to be given during the winter. Students of the hospital are eligible for the office of house-surgeon, or may be appointed clinical assistants. The Secretary, Mr. Robert Newstead, will furnish further information, as may be desired.

**ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, Charing-cross.**—The hospital contains 50 beds; and the patients, who number 10,000 annually, are seen and operations performed daily at two o'clock. The following are the days of attendance of the surgeons: Mr. Power, Monday and Friday; Mr. Rouse, Tuesday and Saturday; Mr. Macnamara, Monday and Thursday; Mr. Cowell, Wednesday and Saturday. The practice of the hospital is open to students. Fees for six months, £3 3s.; perpetual, £5 5s. Students of the hospital are eligible for the post of house-surgeon. Special Demonstrations and Lectures will be given during the session. Secretary, Mr. George C. Farrant.

**ROYAL ORTHOPÆDIC HOSPITAL, 297, Oxford-street.**—Surgeons: Messrs. B. E. Brodhurst, H. A. Reeves, Charles Read, and William E. Balkwill. House-Surgeon: Mr. H. F. Baker. Secretary: Mr. Maskell. Operations on Mondays at 2 P.M. The hospital is open to all legally qualified practitioners. Pupils are admitted to witness the practice of the hospital on the following terms: Six months, £3 3s.; twelve months, £5 5s.; perpetual, £10 10s.

**LONDON SCHOOL OF DENTAL SURGERY, Leicester-square.**—Lectures are delivered in winter on Mechanical Dentistry, by Dr. J. Walker, on Wednesdays at 7 P.M.; on Dental Metallurgy, by Professor Huntington on Tuesdays at 12 o'clock. In summer, by Mr. Coleman, on Tuesdays and Fridays, at 8 A.M., on Dental Surgery and Pathology, and by Mr. Tomes, on Dental Anatomy and Physiology (Human and Comparative), on Wednesdays and Saturdays, at 8 A.M. Fees: General fee for special lectures required by the curriculum, £15 15s.; fee for two years' hospital practice required by the curriculum, £15 15s.; total fees for lectures and practice, £31 10s. Hospital Surgeons: Messrs. Hepburn, Medwin, Gregson, Hutchinson, Moon, and Hill. Assistant-Surgeons: Messrs. Canton, Underwood, Truman, Woodhouse, Storer Bennett, and Parkinson. Chloroformists: Messrs. Clover, Braine, Bailey, and Bird. House-Surgeon:

Mr. Hern. Assistant House-Surgeon: Mr. Cornelius. Medical Tutor: Mr. Morton Smale.

SEAMEN'S HOSPITAL (late *Dreadnaught*), Greenwich, S.E.—This institution is established for the relief of seamen of all nations. Casualties are received at all hours. Apartments are provided in the house of the Surgeon for students and others who may be desirous of studying diseases incidental to tropical climates before entering the services or going abroad. Unusually good opportunities also exist for the practice of operative surgery. There are resident House Physicians and Surgeons. Honorary Consulting Physician: Dr. Robert Barnes, F.R.C.P. Visiting Physicians: Drs. John Curnow, F.R.C.P., and R. E. Carrington. Honorary Consulting Surgeon: Mr. George Busk, F.R.C.S. Eng., F.R.S., &c. Visiting Surgeon: Mr. G. Robertson Turner, F.R.C.S. Medical Officer, Well-street Dispensary: Mr. E. Muirhead Little, M.R.C.S. Principal Medical Officer: Mr. W. Johnson Smith, F.R.C.S. Secretary: Mr. W. Thomas Evans.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond-street, Queen-square, W.C., and Cromwell House, Highgate.—Physicians: Drs. Dickinson, Gee, and W. B. Cheadle. Assistant-Physicians: Drs. R. J. Lee, O. Sturges, Thomas Barlow, D. B. Lees, and Montagu Lubbock. Surgeons: Mr. T. Smith, Mr. Howard Marsh, Mr. Edmund Owen, and Mr. J. H. Morgan. Ophthalmic Surgeon: Mr. Nettlehip. Surgeon-Dentist: Mr. A. Cartwright. Secretary: S. Whitford. There are now 105 beds in the hospital, Great Ormond-street, and 52 beds at the country branch; total 156. In-patients last year, 1050; out-patients, 13,180. The practice at the hospital has recently been thrown open gratuitously to the pupils of the different hospitals and medical schools of London on conditions which may be ascertained of the Secretary.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL.—Established 1752, for the reception of married and single women, the latter with their first child only. The hospital receives annually upwards of 600 women as In-patients, of whom three-fourths are primiparæ, and upwards of 700 Out-patients are attended. Pupils see the practice of both departments. Of 1450 cases delivered since 1879 there were over 250 obstetric complications at birth or shortly after delivery. Physicians to the In-patients: Dr. Hope and Dr. Grigg. Physician to the Out-patients: Dr. Boulton. The physicians attend daily, and give clinical instruction. Medical pupils are received to be trained in Midwifery. Fees: from five guineas. Monthly nurses and midwives are also received for training. Fees: Ten guineas and twenty-five guineas respectively.

BRITISH LYING-IN HOSPITAL, Endell-street, St. Giles's, W.C.—Consulting Physician: Dr. Priestley. Consulting Surgeon: Mr. T. Spencer Wells. Physicians: Dr. Heywood Smith, Dr. S. Fancourt Barnes, and Dr. John Phillips. Matron: Miss Freeman. Secretary: Mr. Fitz-Roy Gardner. This institution receives women only as midwifery pupils. The pupils reside in the hospital, and attend the patients in-doors and within half-a-mile radius, under the direction of the matron and physician. A course of lectures is also given by the physicians. The fee for the course of three months is ten guineas. Pupils that prove themselves competent receive a certificate signed by the physicians, enabling them to practise midwifery.

THE ROYAL HOSPITAL FOR CHILDREN AND WOMEN, Waterloo-bridge-road.—Instituted 1816. Consulting Physicians: Dr. Wilks, Dr. John Williams. Consulting Surgeons: Mr. J. Cooper Forster, Mr. Edwin Canton. Physicians: Drs. W. Park, G. Roper, and Edwin Burrell. Surgeon: Mr. H. C. Jacobson. Assistant-Surgeon: E. Overman Day. Surgeon-Dentist: Mr. W. Whitehouse. Resident Medical Officer: J. F. Briscoe. Secretary: Mr. R. G. Keatin. Advanced students in medicine, and such practitioners as may desire it, are permitted to attend the practice of this hospital gratis. If a certificate signifying such attendance be required, the sum of £5 5s. must be paid to the physicians and surgeons in ordinary conjointly.

VICTORIA HOSPITAL FOR CHILDREN, Chelsea, S.W., and Churchfields, Margate.—The Hospital contains 65 beds and 17 at the home at Margate; and has a large out-patient department (over 500 weekly). Physicians: Dr. Julian Evans and Dr. Ridge Jones. Physician to the out-patients: Drs. Grigg, Albert Venn, T. Colcott Fox, and F. D. Drewitt. Surgeon: Mr. Cowell. Surgeons to the out-patients: Messrs. Churchill and Walter Pyc. Dental Surgeon: Mr. Francis Rex. House-Surgeon: William Arbutnot Lane. Regis-

trar: George Weldon. Secretary: Captain W. C. Blount, R.N. Out patients are seen daily as under:—Medical cases: Daily, except Saturday and Sunday, at 9 A.M.; also on Mondays and Thursdays at 1.30. Surgical cases: Daily, except Monday and Thursday, at 10 A.M. Dental cases: Wednesdays and Saturdays at 9 A.M.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Consulting Physicians: Robert Barnes, M.D.; Andrew Clark, M.D.; Consulting Surgeon: Buxton Shillitoe, Esq. Consulting Ophthalmic Surgeon: George Cowell, Esq. Physicians: Eustace Smith, M.D. Lond.; Horatio B. Donkin, M.B. Oxon. Surgeons: Arthur Caesar, M.R.C.S.; H. A. Reeves, F.R.C.S.E. Assistant Physicians: Francis Warner, M.D. Lond.; H. Radcliffe Crocker, M.D. Lond. Assistant Surgeon: R. W. Parker, M.R.C.S. Administrator of Anæsthetics: Thomas Bird, M.A., M.R.C.S. Medical Officer: J. Scott Battams, M.R.C.S. The hospital contains 92 beds, besides 10 beds in an infirmary for nurses and children who require isolation. The hospital is open free.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—Consulting Physician: Dr. W. S. Playfair. Consulting Surgeon: Mr. Prescott Hewett. Physicians: Drs. Fred. Willcocks, F. Taylor, N. I. C. Tirard, James Goodhart. Surgeons: Messrs. W. Morrant Baker, H. G. Howse, R. Clement Lucas, and C. J. Symonds. Ophthalmic Surgeon: Dr. W. A. Brailey. Dental Surgeon: Mr. Isidore Lyons. House-Surgeon: Dr. W. H. C. Newham. Hon. Secretary: Dr. I. Dobree Chepmell.

SCHOOL OF PHARMACY OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Lectures on Chemistry and Pharmacy by Professor Redwood, Ph.D., F.I.C., F.C.S. Botany and Materia Medica by Professor Bentley, M.R.C.S. Eng., F.L.S. Practical Chemistry: Professor John Attfield, Ph.D., F.R.S., F.I.C., F.C.S., Director of the Laboratories; Wyndham R. Dunstan, F.C.S., Demonstrator; Frederick William Short, Assistant-Demonstrator. The session commences on Monday, Oct. 2nd, at 10 A.M. Application for admission to the School, for prospectuses, or for further information, may be made to the professors or their assistants in the lecture theatre or laboratories, 17, Bloomsbury-square, London, W.C.

SOUTH LONDON SCHOOL OF PHARMACY, 325, Kennington-road, S.E.—Managing Director, Dr. Muter. Daily lectures on Chemistry, Botany, Physics, Materia Medica, Pharmacy, Classics. A special hygienic laboratory for the practical training of Medical officers of health and public analysts. Apply to the Secretary, Mr. W. Baxter. Medical students will find this one of the best training schools for examination purposes in or out of London.

THE PARKES MUSEUM.—This museum has recently been incorporated and will shortly be established in Margaret-street, where excellent accommodation has been found for it. The removal of the museum from its somewhat inaccessible quarters at University College has been rendered necessary by the greatly increased size of the museum, and the ever-increasing demands for space by the Professors of University College. In its new home the museum will be accessible to all students, and we believe it is the intention of the Council to offer facilities to any teacher of Hygiene in a medical school who may wish to bring his class to the museum for instruction. The lectures and demonstrations which were given in the museum with so much success in 1879-1880, but which had to be discontinued in consequence of the overcrowded state of the museum at University College, will be renewed as soon as the reinstating of the museum is accomplished.

## ENGLISH PROVINCIAL HOSPITALS AND MEDICAL SCHOOLS.

BATH ROYAL UNITED HOSPITAL.—120 beds. Honorary Consulting Physicians: Drs. Davies and Coates. Physicians: Drs. Goodridge, Cole, and Fox. Surgeons: Messrs. Stockwell, Fowler, and Freeman. Assistant-Surgeons: Messrs. Green, Scott, and Ransford. Honorary Medical Officers for Out-patients: Dr. Field, and Messrs. Cowan and Craddock. Dental Surgeon: Mr. Gaine. Pathological Registrar and Curator: Mr. H. Cultiford Hopkins. The hospital is recognised by the General Medical Council, and licensed for dissection. It has a good library and an excellent museum, containing a large number of interesting specimens, both in Pathology and Comparative Anatomy.

A year spent at the hospital counts as one out of the four required before qualifying for practice. Fees for attending the hospital practice, six months, £5 5s.; twelve months, £10 10s. Instruction in Practical Pharmacy, £5 5s.

Pupils entering in October can, if desired, be instructed in the subjects required for the First Professional Examination of the Royal College of Physicians, which can be passed during the year spent at the hospital. The subjects are Chemistry and Chemical Physics, Materia Medica and Pharmacy, Medical Botany, and Osteology.

For further particulars apply to the Registrar and Curator.

**QUEEN'S COLLEGE, BIRMINGHAM.**—The Sands Cox Prize, of the value of £20, is offered annually in the Medical Department. It is open to students who have completed their curriculum, and is awarded after examination in Medicine, Surgery, and Midwifery. The examination for this prize in 1883 will be held in the last week in March. Two Ingleby Scholarships will be offered annually after examination in Obstetric Medicine and Surgery, and Diseases of Women and Children. These Scholarships are open to students who have completed the first two years of their curriculum in this College. One or more Sydenham Scholarships will be offered annually, of the value of thirty guineas each. The orphan sons of former students of the Birmingham Medical School shall have priority of election. No Sydenham scholars shall be elected whose age exceeds twenty-three years on the day of election. The Scholarships shall be held for three years, subject to good behaviour. One or more Queen's Scholarships will be offered annually of the value of thirty guineas. They are held for three years, one third being paid each year, subject to good behaviour. Medals and certificates of honour are awarded annually, in each class after examination. Students of Queen's College are qualified to compete for all Scholarships, gold medals, and other prizes offered by the University of London, the Royal College of Surgeons, and the Apothecaries' Society.

**THE GENERAL AND THE QUEEN'S HOSPITALS, BIRMINGHAM.**—*The General Hospital*.—Consulting Physician: Dr. Fletcher. Consulting Surgeons: Mr. Crompton and Mr. Baker. Physicians: Drs. Russell, Wade, Foster, and Rickards. Surgeons: Messrs. Pemberton, Bartleet, Jolly, and Chavasse. Obstetric Officer: Dr. Malins. Assistant-Physicians: Drs. Saundby and Simon. Assistant-Surgeons: Messrs. Archer and Haslam. *The Queen's Hospital*.—Consulting Obstetric Surgeon: Mr. Berry. Consulting Surgeon: Mr. S. Gamgee. Physicians: Drs. Sawyer, Carter, and Hunt. Surgeons: Messrs. West, Furneaux Jordan, Wilders, and Bennett May. Obstetric Surgeon: Mr. John Clay. Ophthalmic Surgeon: Mr. Priestley Smith. Dental Surgeon: Mr. Charles Sims. Physician for Out-patients: Dr. Suckling. Casualty Surgeons: Messrs. Lloyd and Hawkins.

The practices of these hospitals are amalgamated for the purposes of clinical instruction under the direction of the Birmingham Clinical Board. All students will be allotted to each hospital by the Clinical Board, so that they may divide their time equally between the two hospitals.

**BRISTOL SCHOOL OF MEDICINE** (affiliated to University College, Bristol).—Students of Anatomy or Physiology who do not pay the composition fee of sixty guineas are required to pay a medical tutor's fees of two guineas per annum.

**BRISTOL ROYAL INFIRMARY.**—250 beds. Physicians: Drs. Spencer, Shingleton Smith, Waldo, and Shaw. Surgeons: Messrs. Board, Dowson, Pritchard, Cross, and Greig Smith. Surgeon for the out-patients: Mr. Harsant. Medical Superintendent: Mr. Macintire. House-Physician: Dr. Watson. House-Surgeon: Dr. London. Secretary: W. Trenerry. In-patients last year 2863; out-patients last year 30,478. Clinical clerkship, six months, five guineas; one year, eight guineas. Dressership, five guineas for each six months. Obstetric clerkship, three guineas for each three months. Special clinical instruction is given in Diseases of the Eye, Ear, and Throat, also in Diseases of Women. Several prizes, of considerable value, are open to competition among the students.

*Fees.*—Medical or Surgical Practice, six months, seven guineas; one year, twelve guineas; perpetual, twenty guineas. Medical and Surgical Practice together in one payment, one year, twenty guineas; perpetual, thirty-five guineas. The above fees include Clinical Lectures.

Pupils are entitled to attend the practice not only of their own physician or surgeon, but also that of all the physicians

or surgeons. Surgical pupils, on acquiring the requisite experience, are permitted to dress all the out-patients, and also to reside in the house in weekly rotation, where they are in charge of all the casualties under the supervision of the house-surgeon. A Pathological Clerk, who performs all the post-mortem examinations, is appointed for three months from among the senior students. Practical Pharmacy at the laboratory and dispensary. The library contains about 3000 volumes, the museum over 3000 specimens.

**BRISTOL GENERAL HOSPITAL.**—154 Beds. Physicians: Drs. Burder, Skerritt, and Harrison. Physician Accoucheur: Dr. Lawrence. Surgeons: Messrs. Lansdown, Dobson, Kvall, and Pickering. Dentist: Mr. Parson. House-Surgeon: Mr. Penny. Physician's-Assistant: Mr. Woolby. Assistant House-Surgeon: Mr. Ansted. Clinical clerkship, six months, five guineas. Dressership, six months, five guineas. Obstetric clerkship, three months, three guineas. Special clinical instruction is given in Diseases of the Skin, Eye, Ear, and Throat, also in Diseases of Women, and in Dental Surgery. Several valuable scholarships are open to competition.

*Fees.*—Medical or Surgical Practice, six months, £6; twelve months, £10; perpetual, £20. The above fees include Clinical Lectures.

Pupils are entitled to attend the whole medical and surgical practice of the hospital. Dressers re-side in the hospital in rotation, and free of expense, and attend all the casualties under the direction of the House Surgeon. Instruction in Pharmacy is given in the hospital dispensary. There is a good library, and also a museum, to both of which the students have access.

**ADDENBROOKE'S HOSPITAL, CAMBRIDGE.**—Clinical Lectures in Medicine and Surgery in connexion with the Cambridge Medical School are delivered at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery, in the wards and out-patient rooms, is given by the physicians and surgeons daily, during the vacations as well as term time. Instruction is also given in all the special modes of medical and surgical investigation. Clinical clerks and dressers are selected from students according to merit and without payment.

**UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, Newcastle-upon-Tyne.**—*Scholarships, &c.*—A University of Durham Scholarship of the value of £25 a year for four years annually for proficiency in Arts awarded to full students in their first year only. The Dickinson Scholarship, value £15 annually, for Medicine, Surgery, Midwifery, and Pathology. The Tulloch Scholarship, value £20 annually, for Anatomy, Physiology, and Chemistry. The Charlton Scholarship, value £35 annually (together with a gold medal), for Medicine. The Gibb Scholarship, value £25 annually, for Pathology. At the end of each session a Silver Medal and Certificate of Honour are awarded in each of the regular classes. An Assistant Curator of the Museum is annually appointed from among the senior students, and receives £12 as an honorarium. Four Assistant Demonstrators of Anatomy (each receiving an honorarium of £5), Assistant Physiologists, Pathological Assistants, and Assistants to the Dental Surgeon are also elected. Four times in the year, two Resident Medical Assistants, two Resident Surgical Assistants, three Non-resident Clinical Clerks, and sixteen Non-resident Dressers (eight for the In-patients and eight for the Out-patient Department), are appointed for three months. The Medical and Surgical Assistants are provided with apartments and board in the Infirmary, on payment of five guineas for three months.

*Fees for Lectures.*—Composition fee for all the lectures, qualifying for the Licence in Medicine and the Mastership in Surgery of the University of Durham, the Licence and Membership of the Royal College of Physicians, the Membership of the College of Surgeons, and the Licence of the Apothecaries' Society, and payable on entering to the first winter session, or by instalments, 60 guineas. Separate courses of lectures, each £5 5s.

*Hospital Practice.*—This can be attended at the Newcastle Infirmary, which contains 230 beds. Midwifery, Gynaecology, Ophthalmology, Dermatology, Diseases of the Throat and Ear, and Insanity can be specially studied. The Laboratories, Libraries, and Museums are open daily.

*Fees for Hospital Practice.*—Twelve months, £12 12s.; six months, £8 8s.; three months, £5 5s.; perpetual fee, £26 5s.; or, if paid by three instalments, first year, £12 12s.; second

year, £10 10s.; third year, £6 6s. If paid by two instalments, first year £14 14s.; second year, £12 12s. These fees are payable in advance.

**GENERAL KENT AND CANTERBURY HOSPITAL.**—Open for the reception of patients April 26th, 1793. 46,019 in-patients, and 80,048 out-patients, have been admitted since the hospital was open. The hospital contains 102 beds. Pupils of the staff are admitted to the practice of the hospital, and have the use of the library of the East Kent and Canterbury Medical Society, for £7 7s. Operation day, Thursday, 11 A.M. Physicians: Drs. Alfred Lochee and Henry Alexander Gogarty. Consulting Surgeon: Mr. James Reid. Surgeons: Messrs. Charles Holtum, Frank Wachter, Thomas Whitehead Reid, and John Gressley. Dentist: Mr. Martin L. Bell. House-Surgeon: Mr. F. de Courcy Skeete. Assistant House-Surgeon and Dispenser: Mr. H. J. Dyson. Secretary: Mr. Charles H. Read.

**LEEDS GENERAL INFIRMARY** has accommodation for 300 in-patients. Clinical Lectures are given by the Physicians and Surgeons in the theatre of the school, and in the operating-room of the infirmary. All students must hold the office of clinical clerk and dresser, in accordance with the recent requirements of the examining boards. In the Eye and Ear Department a large number of special cases are treated during the year. Demonstrations on Diseases of the Ear are given by Mr. Nunneley.

A house-physician and a house-surgeon are elected from time to time when vacancies occur. There are also four resident assistants in the infirmary. Two are elected every six months, and they continue in office for one year. They are chosen from the senior students of the school, and are provided with apartments and board in the infirmary free of charge.

Dr. Major, Medical Director of the West Riding Lunatic Asylum, lectures on Mental Diseases during the summer.

The Hardwick Clinical Prize, value £10, is conferred annually upon the most deserving student who exhibits a satisfactory proficiency in Clinical Medicine. The Surgeons' Clinical Prizes, value respectively £8, £5, and £3, given by the surgeons to the hospital, are conferred annually on the most deserving students who exhibit proficiency in Clinical Surgery. In addition to the Silver Medal awarded in Medical Jurisprudence, there is a prize of £10 (Thorpe Prize), for which a special examination is annually held. Four resident assistants are chosen from the senior students, board and residence free. There are a large Dispensary and a Fever Hospital in the town, both open to students attending the school.

**LEEDS SCHOOL OF MEDICINE.**—Several of the Courses of Lectures, are now, by arrangement, attended at the Yorkshire College, which is within a short distance of the School of Medicine. This College commenced its operations in 1874, and in addition to the lectures on Chemistry, Biology, Comparative Anatomy, and Botany, attended by students of the Leeds School of Medicine, it now possesses Chairs in various branches of Science and Literature.

**UNIVERSITY COLLEGE, LIVERPOOL** (Royal Infirmary School of Medicine).—Three house-surgeons and two house-physicians are elected every six months from pupils of the school who have obtained a qualification. Nine clinical dressers and nine clerks are elected quarterly; and post-mortem clerks for six weeks. Pupils of the infirmary are admitted to learn pharmacy in the dispensing department for six months. Three scholarships of £21, held for two years, and one of £16. The hospital contains 300 beds; including 40 beds for the treatment of diseases of women. The Lock Hospital adjoining contains 60 beds.

*Fees.*—For six months' medical practice, six guineas; twelve months, seven guineas; surgical, seven guineas for six months, ten pounds for twelve months (this includes admission to the practice of the Lock Hospital adjoining the Infirmary); perpetual medical and surgical practice, forty guineas.

A School of Dental Surgery exists in connexion with the above. The curriculum includes Lectures and Demonstrations on all the subjects required for the Licence in Dental Surgery of the Royal College of Surgeons of London, Edinburgh, and Dublin.

**LIVERPOOL NORTHERN HOSPITAL.**—Physicians: Drs. Dickinson and Caton. Surgeons: Mr. Chauncey Pozey, Dr. Campbell, and Mr. D. H. Harrison. Dental Surgeon:

Mr. J. B. Lloyd. House-Surgeon: Mr. G. S. Hamilton. Assistant House-Surgeon: Mr. W. R. Parker. House-Physician: Dr. C. Shears. 142 beds. There is a special ward for the treatment of children. Clinical lectures are delivered by the physicians and surgeons during the summer and winter sessions. Clinical clerkships and dresserships are open to all the students without additional fee.

*Fees for Hospital Practice and Clinical Lectures.*—Perpetual, twenty-five guineas; one year, ten guineas; six months, seven guineas; three months, four guineas. Students can enter to the medical or surgical practice separately on payment of half the above fees. Practical pharmacy, three months fee, two guineas.

Attendance on the practice of this hospital qualifies for all the examining boards.

**LIVERPOOL ROYAL SOUTHERN HOSPITAL.**—Physicians: Drs. Cameron, Carter, and Williams. Surgeons: Messrs. Hamilton, Little, and Paul. Senior House-Surgeon: Dr. Davison. Junior House-Surgeons: Mr. W. H. Irvin Sellers and Mr. M. M. Fitzpatrick. 200 beds. Clinical lectures are given by the physicians and surgeons during the winter and summer sessions. Clinical clerkships and dresserships open to all students. Special wards for accidents and diseases of children. Rooms for a limited number of resident students.

*Fees for Hospital Practice and Clinical Lectures.*—Perpetual, twenty-five guineas; one year, ten guineas; six months seven guineas; three months, four guineas.

The practice of the hospital is recognised by all examining bodies.

**LIVERPOOL COLLEGE OF CHEMISTRY.**—Founder: Sheridan Muspratt, M.D., Ph.D., F.R.S.E., &c. &c. Principals: Geo. Tate, Ph.D., F.C.S., and Granville H. Sharpe, F.C.S. The chemical lectures will be delivered on Mondays, Tuesdays, Thursdays, and Fridays, commencing October 9th, and continuing until May. Fee four guineas. The chemical laboratories are open from 10 to 5. Fee for practical course for Medical Students, three guineas. Certificates for attendance will be recognised by the chief Medical Examining Boards. Evening courses are also held.

**NORFOLK AND NORWICH HOSPITAL.**—120 beds. One year's attendance recognised by examining boards. *Fees:* For the physicians' practice, five guineas for six months; ten guineas, perpetual. For the surgeon's practice, including dressership, £10 for three months; £15 for six months; £20 for one year; £30 for two years; and £40 perpetual. Pupils, resident and non-resident. Physicians: Dr. Eade, Dr. Bateman, and Dr. Taylor. Surgeons: Mr. Cadge, Mr. Crosse, and Mr. Williams. Assistant-Surgeons: Dr. Beverley and Mr. Robinson. House-Surgeon: Mr. D. D. Day.

**NORTHAMPTON GENERAL INFIRMARY.**—Established 1743; rebuilt 1793. In-patients, 1128; out-patients, 7587. Beds, 144. Physician: Dr. Buzard. Surgeons: Messrs. Kirby Smith and G. H. Percival. House-Surgeon: Dr. A. H. Jones. Resident Medical Officer: Mr. E. J. Morley. Out-pupils are received and have every opportunity of acquiring a practical knowledge of their profession. Instruction is also given in Anatomy and Materia Medica, and Practical Pharmacy. Pupils' fee £25 per annum, or a perpetual fee of £50. The infirmary is recognised by the examining boards.

**OWENS COLLEGE (MANCHESTER ROYAL) SCHOOL OF MEDICINE.**—This medical school is located in a large new building, which forms a part of Owens College. It is provided with a very large dissecting-room, physiological laboratory, private laboratories, and work-rooms, besides lecture-rooms, a museum, and a library. The departments of Anatomy, Physiology, and Chemistry are taught by professors who devote the whole of their time to the duties of their respective chairs. The more strictly practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary, to which are attached a fever hospital, a lunatic asylum, and a convalescent home. Medical and surgical clinical classes are conducted in the infirmary, by the professors of medicine and surgery, and separate instruction is afforded in the elements of medical and surgical physical diagnosis, in obstetric medicine, ophthalmic surgery, and pathological anatomy by the different members of the staff of the medical school and infirmary. The following scholarships and

prizes are open to students of the medical school:—1. A Dauntsey Scholarship of the value of about £100 is offered annually for competition at the beginning of October to persons who have not been students in any medical school in the United Kingdom, and whose ages does not then exceed twenty-five years. The subjects of examination are—(a) General and Comparative Anatomy; (b) Physiological Botany; (c) Chemistry; (d) Mathematics or Latin. 2. A Scholarship and Prizes are awarded at the end of each academic year to students of the first, second, and third year. 3. A Platt Physiological Scholarship of £50 a year for two years is offered annually to the student who, having studied for one entire session in the physiological laboratory of Owens College, has prosecuted the best original investigation in Physiology, and has passed a satisfactory examination in Physiology. 4. Two Platt exhibitions of the value of £15 each, to be competed for by first and second year's students in the class of Physiology. 5. A Dumville Surgical Prize of £20 is offered annually for proficiency in Clinical Surgery. 6. Medical and Surgical Clinical Prizes, each of the value of six guineas, are open to competition each year for the best reports (with comments) of cases which have occurred in the wards of the infirmary.

MANCHESTER ROYAL INFIRMARY.—Consulting Physicians: Drs. R. F. Ainsworth, Frank Renaud, Henry Browne. Consulting Surgeon: Mr. George Bowring. Physicians: Drs. William Roberts, Henry Simpson, John E. Morgan, D. J. Leech. Assistant Physicians: Drs. Julius Dreschfeld and James Ross. Obstetric Physician: Dr. John Thorburn. Surgeons: Messrs. F. A. Heath, Edward Lund, Walter Whitehead, Thomas Jones. Assistant Surgeons: Messrs. James Hardie, Fred. A. Southam. Ophthalmic Surgeon: Dr. D. Little. Dental Surgeon: Mr. G. W. Smith. Resident Medical Officer: Dr. Graham Steel. Resident Surgical Officer: Mr. Edmund H. Howlett. Medical and Surgical Registrar: Mr. G. A. Wright. Pathological Registrar: Dr. Alfred H. Young. Assistant Medical Officers: Drs. S. Moritz and T. J. Wilkinson. General Superintendent and Secretary: Mr. W. L. Saunderson.

The infirmary embraces a nurse-training institution, consisting of a staff of about eighty skilled nurses. It contains 315 beds. The annual average number of out- and home-patients is over 16,000, and the list of casualties in the accident-room exceeds 6000 per annum. The Infirmary, the Barnes Convalescent Home, and the Mossall Fever Hospital contain together 670 beds. The Lunatic Hospital at Cheadle now accommodates 250 patients.

Fees.—Medical practice: three months, four guineas; six months, eight guineas; twelve months, twelve guineas; full period required by the examining board, eighteen guineas. Surgical practice: three months, six guineas; six months, nine guineas; twelve months, eighteen guineas; full period required by the examining board, thirty guineas. The fees for the full period required by the examining boards of both medical and surgical practice may be paid by a composition fee of £42 on entrance, or by two instalments of £22 each at an interval of twelve months.

One medical and one surgical clinical prize, each of the value of six guineas, are offered annually for the best reports and commentaries on medical and surgical cases. Four non-resident and twelve resident officers are appointed. Two or more clinical clerks are attached to each physician and assistant-physician, and two or more dressers to each surgeon and assistant-surgeon. Two clerks are appointed to the pathological registrar and to each of the assistant-medical officers. Accident-room dressers are appointed every month.

SHEFFIELD SCHOOL OF MEDICINE.—The infirmary contains 180 beds; a Museum of Pathology, Library, and Post-mortem Theatre, with microscopes and all the appliances for clinical research. Perpetual fee for attendance on all the lectures required by the Royal College of Surgeons and the Apothecaries' Hall, £47. Secretary, Mr. A. Jackson. A tutor's fee of £2 2s. is required from students entering for Anatomy and Physiology.

JESSOP HOSPITAL FOR WOMEN, Gell-street, Sheffield.—Medical Officers: Dr. Keeling, Dr. Hime, Mr. F. Woolhouse, and Mr. R. Favell. The hospital is devoted chiefly to diseases peculiar to women. There is also an obstetric department attached to the hospital for the admission of a small number of cases. A staff of midwives connected with the hospital attend lying-in women at their own homes, and in case of need are assisted by the members of the medical staff of the

hospital. Out-patients are attended daily at the hospital. Students can attend the practice of the hospital, and be supplied with cases of midwifery. Secretary, H. B. Warner, Hallamshire Chambers, Church-street.

HARTLEY INSTITUTION, Southampton.—In addition to preparations for the Preliminary Examination, instruction is given in Anatomy and Physiology, Zoology, Chemistry, Botany, Practical Chemistry, and in the use of the Microscope. The institution contains a fine collection of anatomical models, and a medical library. The practice of the Royal Infirmary of Southampton is open to students. The course of instruction is recognised by the Royal Colleges of Physicians and Surgeons of London for eighteen months of the four years of professional study required.

Fees £6 6s. per term, or £15 per annum, in advance, which entitle the student to twenty-eight hours' instruction per week, supplemented by the teaching in the Department of General Literature.

NORTH STAFFORDSHIRE INFIRMARY, Hartshill.—The New Infirmary, opened in 1869, is built on the pavilion plan, has accommodation for nearly 220 patients, including detached fever wards, children's wards, and special ovarian wards. In-patients last year, 1501; out-patients, 9398. The attendance of pupils at this Infirmary is duly recognised by all the Examining Boards; and there are unusual facilities for acquiring a practical knowledge of the profession. Physicians and Medical Officers: Dr. J. T. Arldge, Dr. C. Orton, Messrs. Ashwell and J. G. West. Surgeons: Messrs. W. H. Fulker, J. Alcock, and W. D. Spanton. Secretary: Mr. R. Hordley, Hartshill, Stoke-on-Trent, from whom particulars as to fees, &c., may be obtained.

NEWCASTLE-ON-TYNE THROAT AND EAR HOSPITAL.—Senior Surgeon: Richard Ellis, F.R.C.S. Edin. Surgeon: Samuel J. Macaulay, L.R.C.P. Edin., L.F.P.S.G. This hospital is open to students of Medicine on Tuesdays, Thursdays, and Saturdays, on the payment of a small fee.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Founded 1848. Beds, 210. A preparatory school of Medicine and Surgery. The pupils have the advantage of seeing the whole of the practice of the physicians and Surgeons, and are trained in clinical work by the medical and surgical staff. The attendance of pupils at this hospital is recognised by all the examining boards.

Fees.—Six months, £6 6s.; twelve months, £10 10s.; perpetual, £21. Some members of the honorary staff receive resident pupils. For further particulars, apply to the Hon. Secretary of the medical committee.

YARMOUTH HOSPITAL.—Surgeons: Mr. Charles Palmer, Mr. T. Lettis, Mr. D. Meadows, and Mr. A. C. Mayo. House-Surgeon: Mr. P. H. Kidd, M.B., C.M. Edin.

YORK COUNTY HOSPITAL.—Established 1740; rebuilt 1851. 110 beds. In-patients, 704; out-patients, 4283. Physicians: Drs. G. Shann and W. Matterson. Consulting Surgeon: Mr. W. D. Husband. Surgeons: Messrs. R. Hewetson, W. H. Jalland, and F. Shann. House-Surgeon: Mr. Arthur Jefferson. Secretary: Mr. R. Holtby.

## SCOTTISH HOSPITALS AND MEDICAL SCHOOLS.

SCHOOL OF MEDICINE, EDINBURGH.—The lectures qualify for the University of Edinburgh and the other universities, the Royal Colleges of Physicians and Surgeons of Edinburgh, London, and Dublin, and the other medical and public boards.

In accordance with the statutes of the University of Edinburgh any four of the medical classes required for graduation, or two complete *Anni Medici*, may be attended in this school, each of which *Anni Medici* may be constituted by attendance on two of the six months' courses, or on one of these and two three months' courses. The regulations require that the fee for any class taken for graduation in Edinburgh be the same as that for the corresponding class in the

University. The whole education required for graduation at the University of London, may be taken in this school.

*Fees.*—For a first course of lectures, £3 5s.; for a second, £2 4s.; perpetual, £5 5s. To those who have already attended a first course in Edinburgh the perpetual fee is £2 4s. Practical Anatomy (six months' course), £3 3s.; course of demonstrations, £2 2s.; perpetual, £4 4s. Practical Anatomy with course of demonstrations, £4 4s. Practical Chemistry, £3 3s. Analytical Chemistry, £2 a month, £5 for three months, or £10 for six months. Practical Materia Medica, including Practical Pharmacy and Diseases of the Ear, Diseases of Children, Diseases of the Skin, each £2 2s. Vaccination, £1 1s. For summer courses of Clinical Surgery and Clinical Medicine, each £2 4s.; Practical Anatomy, including Anatomical Demonstrations, Operative Surgery, and Practical Medicine, and Medical Diagnosis, each £2 2s.; Insanity, £1 1s. The minimum cost of the education in this School of Medicine for the double qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons, including the fees for the joint examination, is £95; whilst the minimum cost for the single qualification of either Physician or Surgeon, including fee for examination, is £85.

**EDINBURGH SCHOOL OF MEDICINE**, Marshall-street, Nicholson-square.—The classes of this School will be resumed for the Winter Session on the 24th October. Chemistry, Theoretical and Practical, Midwifery, Surgery and Medicine. From the Dispensary attached to this Institution, Pharmacy, Practical and Theoretical, Practical Midwifery, Out-door Practice, and Surgical Diagnosis. Attendance at this institution qualifies for the University of Edinburgh and all other Licensing Boards. Tutorial Classes in all the branches of the medical curriculum. Preliminary Medical Classes, L. H. Wright, M.A., 11 A.M. to 4 P.M.; Theoretical Chemistry, Dr. Drinkwater, 10 A.M. to 11 A.M.; Theoretical Midwifery, Dr. C. Bell, 11 A.M. to 12 A.M.; Theoretical Pharmacy, R. Urquhart, 3 P.M. to 4 P.M.; Class for Surgical Diagnosis, Dr. Miller, 3 P.M. to 4 P.M.; Practical Midwifery and Out-door Practice at the Dispensary, 2 P.M. to 4 P.M.; Practical Pharmacy, 2 to 4 and 7 to 8 P.M.; Practical and Analytical Chemistry, 9 A.M. to 5 P.M.; Class for Practical Medicine, Dr. A. Smart, 2 P.M. to 3 P.M. The Pharmaceutical Section of this School will open on Oct. the 3rd. Particulars of R. Urquhart, Secretary.

**ROYAL INFIRMARY, EDINBURGH.**—Beds are set apart for clinical instruction by the professors of the University of Edinburgh. Courses of Clinical Medicine and Surgery are also given by the ordinary physicians and surgeons. Special instruction is given in the medical department on Diseases of Women, Physical Diagnosis, &c., and in the surgical department on Diseases of the Eye. Separate wards are devoted to fever, venereal diseases, diseases of women, diseases of the eye, also to cases of incidental delirium or insanity. Post-mortem examinations are conducted in the anatomical theatre by the pathologist, who also gives practical instruction in Pathological Anatomy and Histology. From and after the commencement of the winter session, 1882-3, the fees shall be as follows, viz.:—Perpetual ticket in one payment, £12; annual ticket, £6 6s.; six months, £4 4s.; three months, £2 2s.; monthly, £1 1s. Separate payments amounting to £12 12s. entitle the student to a perpetual ticket. No fees are paid for any medical or surgical appointment. The appointments are as follows:—1. Resident physicians and surgeons are appointed, and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Non-resident clinical clerks are appointed by the physicians and surgeons for such periods and under such conditions as they deem expedient. 3. Each surgeon appoints from four to nine dressers, the appointment being for six months. 4. Assistants in the Pathological department are appointed by the pathologist.

**ANDERSON'S COLLEGE, GLASGOW.**—The following courses are given: In winter, Senior Anatomy, Dr. Buchanan, 4 P.M.; in summer, Osteology, Dr. Buchanan, as may be arranged; Public Health, Dr. Christie, 1 P.M.; Aural Surgery, Dr. Barr, Thursday, 3 P.M.; Practical Medical Chemistry, Mr. Dittmar, Tuesday, Wednesday, and Thursday, 4 P.M. Dental Anatomy (in summer), Dr. D. Taylor, Wednesday and Friday, 8 A.M. Dental Surgery (in summer), Mr. J. R. Brownlie, Tuesday and Thursday, 8 A.M.;

Mechanical Dentistry (in winter), Mr. Woodburn, Thursday, 8 P.M. The Chemical Laboratory is open daily from 10 to 5. Students of the College are admitted to the practice of the Ophthalmic Institution on payment of a matriculation fee of 5s.

*Fees.*—Each course of lectures (except Anatomy), first session, £2 2s.; second session, £1 1s.; afterwards free. Anatomy (including Dissecting-room), first session, £4 4s.; second session, £4 4s.; third session and perpetual, £1 1s.; summer (including Practical Anatomy), £1 1s.; Practical Anatomy only, £1 1s.; Osteology, £1 1s.; Dental Courses, each £2 2s. Fee for two years' curriculum at Dental Hospital, £10 10s. Students who have attended classes at other schools will be admitted to such classes as they may have attended elsewhere at reduced fees. Fees for all the Lectures and Hospital Practice required of candidates for the diplomas of Physician and Surgeon, £48.

*Scholarships, &c.*—A Medical Scholarship of £10 for students entering on their second winter. Subjects: Anatomy (bones, joints, muscles, alimentary canal, and heart); Chemistry (general principles; non-metallic elements, and the following metals—viz., potassium, sodium, calcium, magnesium, zinc, aluminium, iron, manganese, and mercury; carbo-hydrates; alcohols, aldehydes, and acids of the fatty series). Prizes of £5 in classes of junior Anatomy and Chemistry.

*Kerr Bursary in Anatomy*, tenable for three years (provided the holder continues to study anatomy during that time). This bursary will be awarded at the close of the winter session to the student of the junior anatomy class who will pass the best examination in the subjects embraced in the lectures.

A Dispensary is connected with Anderson's College. Students have the privilege of visiting and treating patients at their own homes, being assisted by a specially appointed qualified practitioner.

**GLASGOW ROYAL INFIRMARY SCHOOL OF MEDICINE.**—The winter session will open on November 1st. Courses of lectures are given on all the subjects required by the licensing bodies for qualification, and lectures and demonstrations are also given on Practical Physiology, Operative Surgery, Aural Surgery, Dental Surgery, and Diseases of the Eye. During summer, lectures on Insanity are given by Dr. A. Robertson, and the City Asylum under his charge is free to students of this school. Students have unusual facilities for the study of anatomy, the supply of subjects being practically unlimited.

*Class Fees.*—For each course, first session, £2 2s.; second session, and perpetual, £1 1s. Students who have attended a first course elsewhere can enter on the second course on payment of £1 1s. Anatomy: First winter session, £4 4s.; summer session, £1 11s. 6d.; second winter session, £4 4s.; afterwards the fee for lectures and practical anatomy is £1 11s. 6d. per session. Lectures on Diseases of the Ear, £1 1s.; with clinique to those not students of the hospital, £2 2s. Dental Dispensary free to students of the hospital; to others, £5; first year, perpetual, £10. Lectures on the Eye, £1 1s.

**GLASGOW ROYAL INFIRMARY.**—Number of beds, 532. In addition to the ordinary medical and surgical wards, there are separate wards for the treatment of venereal diseases and the diseases of women, whilst Diseases of the Eye, Ear, Throat, and Teeth are specially treated at the dispensary. Courses of clinical medicine and surgery are given by the physicians and surgeons; instruction in pathological anatomy and histology is given by the pathologist.

*Appointments.*—There are five physicians' and five surgeons' assistants. These appointments can be held for six or twelve months, and are open for students who have passed all their examinations except the last, or to gentlemen who have a qualification in medicine or surgery. Clinical assistants, dressers, dispensary clerks, and pathological assistants are selected from the students without additional fee.

*Fees for Hospital Practice and Clinical Lectures.*—First year, £10 10s.; second year, £10 10s.; afterwards free. For six months, £6 6s.; three months, £4 4s. Students who have paid twenty guineas at another hospital for its perpetual ticket are admitted six months for £2 2s., or one year for £3 3s. Vaccination certificate, £1 1s.

**GLASGOW HOSPITAL AND DISPENSARY FOR THE DISEASES OF THE EAR**, 239 and 241, Buchanan-street.—Senior Consulting Physician: Dr. P. Stewart. Senior Consulting Surgeon: Dr. James Morton. Consulting Dental Surgeon:

Dr. J. Cowan Woodburn. Physicians: Dr. A. K. Irvine, Dr. A. L. Kelly, Dr. J. Gardner. Aural Surgeon and Lecturer on Aural Surgery: Dr. James Patterson Cassella. Clinical Assistant: Dr. James Erskine.

This institution is supported by public and voluntary subscription, its object being the advancement of this special department of medical science by lectures and clinical teaching to students, and the gratuitous treatment of poor persons suffering from all forms of ear disease and deafness. Number of cases treated annually 3600.

The hospital, which contains 15 beds for in-door patients, is always open for urgent cases. Hours of surgeons' visit, 3 P.M. daily; clinical teaching daily. Out-door patients are seen on Tuesdays, Wednesdays, Thursdays, and Fridays, at 2 P.M., by Dr. Cassella and assistant; and operations and special demonstrations to students and practitioners on Wednesdays and Thursdays, from 3 to 4 P.M. Adam Sutherland, 75, West Nile-street, Secretary and Acting Treasurer.

GLASGOW WESTERN MEDICAL SCHOOL, University-avenue, Hillhead.—The winter session will open on November 1st. The school is situated close to the Western Infirmary, where students obtain their Hospital Practice and Clinical Lectures. The class-rooms have been newly arranged and enlarged. The attention of students is directed to the unusual facilities presented for the study of practical anatomy and operative surgery, the supply of subjects being practically unlimited. The dissecting-rooms are open for work from the beginning of October till the end of July.

The lectures qualify for the University of Glasgow, the Faculty of Physicians and Surgeons, Glasgow, and the other corporations.

*Class Fees.*—For each course of lectures, first session, £2 2s.; second session, £1 1s. Students who have attended a first course elsewhere pay £1 1s. Anatomy, including practical anatomy, £4 4s. Summer session, £1 11s. 6d.

ABERDEEN ROYAL INFIRMARY.—Contains about 250 beds. Consulting Physician: Dr. A. Harvey. Physicians: Drs. J. W. F. Smith-Shand, R. Beveridge, Angus Fraser. Physicians' Assistant: Dr. D. R. McKinnon. Consulting Surgeon: Dr. W. Pirrie. Surgeons: Messrs. A. Ogston, J. O. Will, R. J. Garden, and John Hall. Surgeons' Assistant: Dr. William Sinclair. Ophthalmic Surgeon: Dr. Alex. D. Davidson. Pathologist: Dr. James Rodger. Chloroformist: Dr. P. Blaikie Smith. Dental Surgeon: Dr. Williamson. Resident Superintendent and Apothecary: Dr. E. W. Robertson. Pathologist and Curator of Museum: Dr. J. Rodger. Treasurer and Secretary: Mr. W. Carnie.

THE ABERDEEN ROYAL LUNATIC ASYLUM contains about 540 beds. Physician: Dr. Robert Jamieson.

## IRISH HOSPITALS AND MEDICAL SCHOOLS.

QUEEN'S COLLEGE, CORK, SCHOOL OF MEDICINE.—The building is provided with a very large, well-ventilated dissecting-room, with physiological and toxicological laboratories, materia medica, anatomical and pathological museums, as well as a room for surgical and obstetrical instruments and appliances. There are well-appointed physical and chemical laboratories, and a large natural history museum in the adjoining building; and part of the College ground is laid out as a botanical garden. The plant houses are now completed and well filled with plants, and are open to the students in the class of Botany.

*Fees.*—For Practical Anatomy, £3; for Practical Chemistry, £3 each course; for Anatomy and Physiology, £3 first course, and £2 for each subsequent course. Other medical classes, £2 first course, and £1 each subsequent course. Eight scholarships (value about £30 each) as well as several exhibitions and class prizes are awarded every year.

Clinical instruction is given at the North and South Infirmaries, and at the Lying-in Hospital; students can also attend the Mercy General Hospital, the Maternity, the Children's Hospital, and the Eye and Ear Infirmary. Fee for clinical lectures and attendance at either the North or South Infirmary, eight guineas for twelve months; five guineas for six months. Clinical instruction can now be given to the students of Queen's College, Cork, by the resident medical superintendent of the Cork District Lunatic Asylum, which contains about 700 patients.

SIR PATRICK DUN'S HOSPITAL, Dublin (in connexion with the School of Physic).—Consulting Surgeon: Dr. William Colles. Physicians: Drs. John Mallet Purser, J. Magee Finny, J. R. Kirkpatrick (Midwifery Physician). Surgeons: Drs. Charles Ball, Edward H. Bennett, Thomas Evelyn Little, Richard G. Butcher (University Lecturer in Operative Surgery). The hospital is visited daily by each of the physicians and surgeons on duty.

The payment of £3 3s. to the hospital entitles any student to attend the clinic of the hospital for twelve months, and to attend the lectures delivered by Dr. R. G. Butcher, University Lecturer in Operative Surgery. Students who have taken out the degrees of Bachelor in Medicine and Master in Surgery in Trinity College are entitled to attend the hospital as perpetual free pupils.

Clinical Lectures are delivered in the hospital theatre at ten o'clock on Mondays and Tuesdays. In addition to the hospital fee, the payment of a fee of £9 9s. is required for the privilege of attending these lectures. Total fees for hospital and lectures for twelve months, £12 12s.

*Sir Patrick Dun's Maternity.*—Total fees for college students, £3 3s. Total fees for externs, £6 6s.

THE ADELAIDE MEDICAL AND SURGICAL HOSPITALS, Peter-street, Dublin.—Fee for nine months' Hospital attendance, £12 12s. Six months', £8 8s. Summer three months', £5 5s.

Three resident pupils are selected half-yearly. At the termination of the session, prizes in Clinical Medicine and Surgery, in Obstetric Medicine, and in Ophthalmic Surgery will be awarded.

*Hudson Scholarship.*—In addition to the junior prizes, the Hudson Scholarship, £30 and a gold medal, as well as a prize of £10, together with a silver medal, will be awarded at the end of the session for proficiency in Clinical Medicine and Medical Pathology; Clinical Surgery and Surgical Pathology; Pathological Histology; Surgical Appliances, including instruments and bandaging; Ophthalmology and Gynaecology.

The certificates of attendance are recognised by all the Universities, Colleges, and Licensing Bodies in the United Kingdom. Physicians: Drs. Henry H. Head and James Little. Surgeons: Dr. John K. Barton, Mr. Benjamin Wills Richardson (Vice-President, Biological Association, University of Dublin), and Dr. Kendal Franks. Obstetric Surgeon: Richard Dancer Purefoy, M.B., F.R.C.S.I. Ophthalmic and Aural Surgeon: H. Rosborough Swanzy, M.A., M.R. Dental Surgeon: Dr. R. Theodore Stack. Assistant-Physician: Wallace Beatty, M.B. and B.Ch., T.C.D.

LEDWICH SCHOOL OF SURGERY AND MEDICINE, Peter-street, Dublin (formerly original School of Anatomy, Medicine, and Surgery).—There are endowments in favour of students, subject to conditions prescribed by the founder, in the following departments:—Two in Anatomy and Physiology; two in Minute Anatomy; two in Practical Anatomy; one in Surgery. Certificates of attendance on these lectures are received by the various examining boards; by the Apothecaries' Halls of Dublin and London; by the King and Queen's College of Physicians in Ireland; by the Royal Colleges of Physicians, London and Edinburgh; by the Royal University, the Universities of Dublin, London, and Glasgow; by the Glasgow Faculty of Physicians and Surgeons and by the Queen's University in Ireland. The Senate of the Royal University having recognised the lectures of this school, arrangements have been made to educate students for its Medical and Surgical Degrees in accordance with its requirements. This school is in a central situation, and is replete with every convenience for study, and successful instruction. By its teachers it is connected with nine hospitals, four of which are Medical and Surgical hospitals, one for Fever, one for Midwifery and Diseases of Women and Children, one for Diseases of the Eye and Ear, &c.

DUBLIN CARMICHAEL COLLEGE, Aungier-street, Dublin.—The following scholarships, &c., are awarded to students entering for an *annus medicus* for the current year:—The Carmichael Scholarships, value £15 and £10; the Mayne Scholarships, value £15 and £5; Class Prizes, £10, £5, £3, and £7, £4, and £2; also Lecture Prizes, value £3.

DR. STEEVENS'S HOSPITAL.—The Medical School formerly attached to the hospital having been discontinued, the medical officers have determined to devote all their energies

to the advancement of Clinical Instruction, and to render it thoroughly practical; for the attainment of which object this hospital affords exceptional advantages. There is a ward entirely devoted to Syphilitic Disease, a detached building for Fever cases, an extensive Out-patient Department, with separate Clinics for Diseases of the Skin, Throat, Teeth, and those peculiar to Women. To each pupil is assigned one or more beds, for the care of which he will be responsible; and he will be expected to keep accurate notes of the cases occupying his bed or beds. At the end of each hospital year gold medals will be awarded for general attention and proficiency in clinical work and case-taking. The hospital, which contains 250 beds, and is provided with distinct wards for the treatment of Fevers and Syphilis, is visited daily, at half-past eight A.M., by the resident surgeon, and at nine A.M. by the physicians and surgeons. The Surgical wards are also visited each evening. Clinical Lectures are given by the physicians and surgeons during the session. Surgical operations are performed on Saturdays, at ten A.M., except in cases of emergency. There is accommodation in the hospital for two medical and six surgical resident clinical assistants. The museum is open daily to the pupils of the hospital. There is also a lending library, containing every modern medical and surgical work. Instruction is given in Practical Pharmacy.

**Fees.**—Hospital Practice: Nine months, £12 12s.; six months, £8 8s.; three months, £5 5s. Dressership.—Winter six months, £21; summer, do., £15 15s.

**MATER MISERICORDIE HOSPITAL, DUBLIN.**—Physicians: Drs. C. J. Nixon, J. M. Redmond, and M. A. Boyd. Assistant Physician: Mr. J. Murphy. Consulting Surgeon: Dr. F. R. Cruise. Surgeons: Messrs. P. T. Hayes, C. Coppinger, and M. J. Kilgarriff. Assistant Surgeon: Mr. H. Kennedy. Obstetric Physician: Dr. T. M. Madden. Ophthalmic Surgeon: Mr. Coppinger. This hospital contains 230 beds, 50 beds being specially reserved for patients suffering from fever and other contagious diseases. Two Clinical Lectures will be delivered in each week, in addition to the daily bedside instruction. The Clinical Lectures will commence on Monday, the 30th October, at 11 o'clock, A.M., when the Introductory Lecture will be delivered by Mr. Kennedy. A special course of lectures and instruction on Fever will be given. A certificate of attendance upon this course, to meet the requirements of the King and Queen's College of Physicians, may be obtained. A ward has been assigned for the treatment of Ophthalmic Diseases. Opportunities are afforded for the study of Diseases of Women in the ward under the care of the Obstetric Physician, and at the dispensary held on Wednesdays and Fridays during the session. Lectures on Clinical Gynaecology will be delivered on Wednesdays at 11 A.M. "Leonard Prizes" (Clinical): Prizes of the value of thirty pounds will be given at the end of the winter session, in accordance with the directions contained in the will of the late Mark Leonard, Esq. Certificates of attendance upon this hospital are recognised by the Royal University and all the Licensing Bodies in the United Kingdom. Terms of attendance: Nine months, £12 12s.; six winter months, £8 8s.; three summer months, £5 5s.

**COOMBE LYING-IN HOSPITAL, AND GUINNESS DISPENSARY FOR THE TREATMENT OF DISEASES PECULIAR TO WOMEN.**—Master: George H. Kidd, M.D., F.R.C.S.I. Deputy-Master: William Roe, M.D., F.R.C.S.I. Assistant-Masters: W. C. Neville, M.A., M.D., M.Ch.; J. S. Poole, M.D., M.Ch., L.M.K.Q.C.P.I. Registrar: Mr. W. Lindsay Beatty. The hospital contains sixty-five beds, and has also a large Extern Maternity attached. Nearly 3000 confinements are attended annually by the pupils of the hospital. A special Dispensary for Diseases peculiar to Women is held daily, and clinical instruction given. The certificates of the hospital are recognised by all licensing bodies, and its diploma is accepted by the Local Government Board, &c. Students can enter at any time. Further particulars can be learned from the registrar, or any of the medical staff.

**ROTUNDA HOSPITALS, Rutland-square, Dublin.**—This institution consists of two distinct hospitals—namely, the Lying-in Hospital and the Auxiliary Hospital, for the reception of patients suffering from uterine and ovarian diseases. There is also a large extern maternity in connexion with the hospital, and a dispensary for diseases peculiar to women, which is open daily. Accommodation is provided for a limited number of intern pupils. Two courses of lectures are given yearly.

## MEDICAL TEACHERS.

**DR. ALDRED, Dore, Sheffield,** a late Oxford Examiner, having had eight years' experience, prepares gentlemen, *visu voce* or by correspondence, for the Preliminary, Public Schools, and Universities.

**Messrs. BAILLY and COATES** prepare candidates for Matriculation, Apothecaries' Hall, College of Preceptors, and all other English, Scotch, and Irish Medical Preliminary Examinations. — The City Institute, 30-32, Ludgate-hill, E.C.

**Mr. J. BECKTON, C.M.,** prepares candidates for the London Matriculation, Medical and Law Preliminary, University, Local, and other Examinations. — 29, Keppell-street, Russell-square, W.C.

**Mr. F. W. BROWN, M.S.C.I.,** coaches in Chemistry, Botany, Materia Medica, and Physics for L.R.C.P. and L.S.A. Examinations, &c.; also for Medical Preliminary, Matriculation, London, Preliminary Scientific, and other Examinations, privately or in class. — 18, Chippenham-road, St. Peter's Park, W.

**Mr. L. BRYAN, M.A. Cantab.,** continues for the tenth year his most successful preparation for Matriculation, Apothecaries' Hall, College of Surgeons, &c., privately and in class. Fees moderate and inclusive. — Chambers, 16, Clifford's-inn, Fleet-street.

**Dr. COALES, LL.D., M.A.,** has for twenty years prepared for the London University Matriculation, Preliminary Examinations of the College of Surgeons, and Apothecaries' Hall. — 119, Gower-street, W.C.

**Mr. JOHN C. COOKE, B.A.,** who has passed many pupils, is about to recommence preparation, in class and privately, for Matriculation. Special facilities offered to the backward and unsuccessful. — 44, Islington-street, Camden-road, N.W.

**Mr. THOMAS COOKE'S School of Anatomy, Physiology, and Surgery** is intended to meet the requirements of two distinct classes of Students—i.e.: (1) Advanced students and qualified practitioners, who may wish either to extend their knowledge of the foregoing subjects or to recall to mind what they once knew and have since forgotten; (2) Beginners entering upon their medical studies by a short term of apprenticeship. For the former, rapid advanced classes, complete in three months, but still thoroughly practical, are provided; and for the latter, when required, more elementary classes of six months' duration. Private address: 16, Woburn place, Russell-square.

**Mr. ROWLAND H. COOMBS, L.R.C.P. Lond.,** trains youths for entrance at a Medical School, with the advantages of practical instruction at a General Infirmary of 100 beds. Pharmacy taught. References to parents and pupils. — Redburn, Spring-grove, St. Cuthbert's, Bedford.

**Mr. A. H. DAWES, 1st B.A. Lond.,** gives lessons privately, in class or by post, in preparation for the London Matriculation and Medical Preliminary Examinations. — 11, Burton-crescent, W.C.

**Dr. EBERLE (Thirsk, Yorks),** late Principal of the Easingwold Medical College, Author of "Students' Medicine," &c. &c.—Gentlemen prepared for the Preliminary Examination in Arts of the Universities, any of the Professions and Services, also for the Primary, Pass, and Competitive Examinations. Personal and special attention directed to the assistance of Practitioners, Assistants, and others, by letter.

**Dr. N. HEINEMANN, F.R.G.S., F.R.Hist.Soc.,** prepares for the Preliminary Examinations &c. — 80, Upper Gloucester-place, Portman-square, London.

**Dr. CRESSWELL HEWETT,** who has himself passed twice first in the competitive examinations, will in future conduct Dr. Power's classes for preparation for the Army and Public Medical Services. — 9, Craven-road, Lancaster-gate.

**Mr. G. HIND, F.R.C.S.,** will resume his Anatomical, Surgical, &c. Demonstrations and Examinations on September 25th, at 5 P.M., at 29, Newman-street, Oxford street, W.C.

**Mr. C. IRVING, Long Benington, Grantham,** prepares for the Matriculation, London, or for the Hall, College, or Physicians, Preliminary Arts Examination, as well as gives Elementary Technical Tuition.

**Mr. THOMAS LYLE, M.A., F.R.Hist.Soc.,** of the London and Dublin Universities, prepares gentlemen, resident and non-resident, for the various Preliminary Arts Examinations and Matriculation at the London University. — Grove House, Shackleton-lane, London, N.E.

**Dr. A. C. MAYBURY, D.Sc. Lond., M.R.C.S., A.R.S.M., F.G.S.,** Lecturer, London Matriculation Classes, St. Thomas's Hospital, Professor of Chemistry, City of London College and Charterhouse Science School, and of Physiology at the Polytechnic, reads with candidates for the Medical and Science Examinations of the University of London, Colleges of Physicians and Surgeons, Apothecaries' Hall, the Army and Navy Medical Services, M.D. Brussels and St. Andrews, &c. — 23, Charlotte-street, Bedford-square, W.C.

**Mr. MURRAY, B.A.,** Arkton House, Wray-crescent, Tollington-park, N., prepares for the Preliminary Examination at the Royal College of Surgeons and Apothecaries' Hall, and the Matriculation at the University of London.

**Mr. J. W. SAUNDERS, A.P.S., G. S. T.,** prepares gentlemen for Examination in Anatomy, Physiology, Botany, Chemistry, Materia Medica, Pharmacy, &c. — 8, High-street, Camden-town, N.W.

**Mr. C. WAITE** prepares Pupils for Matriculation, Preliminary Scientific, and the Examinations for Medical Registration of all the Licensing bodies. — Lonsdale Chambers, 27, Chancery-lane.

**Mr. F. A. WHITE (Classical and Mathematical Honours, Camb.)** prepares pupils for the Matriculation at the London University, and for the Examinations at the Royal College of Surgeons, and Apothecaries' Hall. — 63, Westmoreland-road, Westbourne-park, W.

**Mr. J. WOODLAND, F.L.S., F.G.S.,** Central School of Chemistry, 173, Marylebone-road, N.W., holds classes in Practical and Theoretical Chemistry, Chemical Physics, Materia Medica, and Botany, for the Examinations of the Royal College of Physicians and Apothecaries' Hall, also for the M.B. Degree of the different Universities.

**Dr. A. WRIGHT, The Hawthorns, Finchley, N.,** directs and supervises the professional studies of candidates for Medical Examinations.

## EDUCATIONAL VACCINATING STATIONS.

In order to provide for the granting of those special certificates of proficiency in vaccination which are required to be part of the medical qualification for entering into contracts for the performance of public vaccination, or for acting as deputy to a contractor, vaccination stations in London and the large towns are open, under certain specified conditions, for the purposes of teaching and examination. The public vaccinators officiating at these stations are authorised to give the required certificates of proficiency in vaccination to persons whom they have sufficiently instructed therein.

## To Correspondents.

WE tender our best thanks to those gentlemen who have kindly supplied us with the returns and prospectuses upon which the information given in this Students' Number of THE LANCET relative to the various medical examining bodies, hospitals, and medical schools of the United Kingdom is based.

The present number being almost exclusively devoted to information especially interesting to students, we are necessarily compelled to defer the publication of communications on other important subjects.

### "EXAMINATION MARKS IN SCOTLAND."

To the Editor of THE LANCET.

SIR,—As an Edinburgh man, I cannot let the statement of "Medicus" in your issue of the 26th ult.—"that in Edinburgh the percentage for a pass is 40, whilst above 50 gives honours"—pass unchallenged. This is a misstatement. The system of marking (*vide* Edin. Univ. Calendar, the only official authority on the subject) is carried on by letters and the abbreviations of words—S for satis, and so on. To these none except the examiners can attach a percentage. That the percentage is high, the fact that few, compared with the number who get first-class honours in the various classes, obtain distinction in the professional examinations would tend to indicate. With regard to the long lists of students successful in their class examinations, I fail to see that that indicates a low standard of marking any more than it might equally show a high standard of students' industry and attainments.

I am, Sir, yours sincerely,

Kent, August 30th, 1882. ERNEST F. NEVE, M.B., &c.

To the Editor of THE LANCET.

SIR,—Having noticed in an anonymous communication in your issue of the 26th ult. on the above subject, I would ask your correspondent his authority for the statement, "In Edinburgh the percentage for a pass is 40, while above 50 gives honours." The Calendar gives the only official and authentic information on the subject, and that does not give the percentage in figures. Hence I am driven to the supposition that "Medicus" has stated as a fact that which exists solely in his own aberrant imagination.—I am, Sir, sincerely yours,

Durham, August 30th, 1882. JOHN HERN, M.B. Edin., &c.

### TUBERCULAR DISEASE.

To the Editor of THE LANCET.

SIR,—There is one aspect of the recent discoveries with regard to tubercular disease which I think should be pointed out before the recent ideas on the subject are forgotten, and the controversy with regard to it passes into a new phase. The most generally accepted opinion has been that consumption was a condition of the lungs which might arise from a variety of causes, and might pass by insensible gradations into a variety of other conditions. It was held that ordinary bronchitis or pneumonia might pass into tubercular consumption under certain circumstances, and that there was no line of demarcation between the pathological processes operating in each case. In connexion with these ideas the words "caseous" and "catarrhal" pneumonia were invented and used. Others held that this view was arrived at by giving too great an attention to the microscopical appearances, and by not taking a general view of the facts regarding the disease. They looked upon the results of consumption as due to a specific and definite disease, which they gave the name of *tubercular*, and upon consumption, as accompanied by a special growth or deposit, which they called *tubercle*. Which was most right in the conclusion they drew from the evidence then before them? Koch's observations seem to say decidedly the latter.

I am, Sir, yours, &c.,

Cape Town, August 8th, 1882.

H. S.

*Dr. Pirrie's Resignation.*—The vacancy created by the resignation of Dr. Pirrie will doubtless be filled before the commencement of the ensuing winter session. The patronage of the chair is vested in the Crown. Dr. Pirrie has, we believe, been Regius Professor of Surgery in the University of Aberdeen for forty-three years.

*The Fellows' Association.*—Our correspondent should seek the support of some of his influential associates. We agree that if the meetings of the Association be held as originally proposed, their influence may be prejudicial both to the College and to medical education generally.

*Universitas.*—Our correspondent should consult Dr. Hardwicke's "Medical Education and Practice in all Parts of the World" (Churchill).

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Wyld, London; Dr. Kirkwood; Dr. Thursfield, Leamington; Lieut.-Col. Duncan; Dr. Hovell, London; Dr. Leadliff, Brighton; Dr. Donaldson, Londonderry; Mr. Inglesant, Spondon; Mr. Saunderson, Manchester; Dr. Muir, Thornhill; Mr. Firth, Blackburn; Dr. Hilles, Gargrave; Mr. Foster, Leeds; Mr. Marlin, Elgin; Mr. Craske; Mr. Bagshaw, Salford; Mr. Beal, Brighton; Captain Hobson; Mr. Western, Bath; Surgeon-Major Hopkins, Leeds; Mr. Cooke, Powick; Dr. Cresswell, Birmingham; Mr. Dixie, London; Mr. Stuart, Dublin; Mr. Moutray, Honduras; Mrs. Elgar, Plymouth; Messrs. ### SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year.....£1 13 6 | Six Months .....£0 10 6

TO CHINA AND INDIA ..... One Year, 1 16 10

TO THE COLONIES AND UNITED STATES.. Ditto, 1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

## Clinical Lecture

ON THE

## CURABILITY OF ACUTE TUBERCULOSIS.

*Delivered at the Westminster Hospital.*

BY OCTAVIUS STURGES, M.D.,

PHYSICIAN TO THE HOSPITAL.

GENTLEMEN,—The case I propose bringing before you involves a curious problem of practical medicine in the nature of a dilemma. Acute tuberculosis is represented to us from the anatomical point of view as a disease which is uniformly fatal. At the bedside, however, we meet with examples, indistinguishable from acute tuberculosis, which nevertheless recover. Are we to say of these that our diagnosis has been in error, or that the statement of the uniform fatality of acute tuberculosis is not without exception? Is it more probable that the diagnosis is wrong or the treatment curative? If the diagnosis be in error, how may such errors be avoided in the future? If it be the treatment that makes all the difference, in what manner is such treatment to be employed, what is the evidence of its efficacy, and to what stage of the disease does it apply? I need not say that questions like these are of the highest practical interest. They are so from the pathological side, owing to the very intimate likeness between acute tuberculosis and enteric fever. They are so still more from the treatment side, owing to the assertions of some that the hypophosphites of lime and soda are directly curative of acute tuberculosis.

Now the case shortly summarised from the notes of Mr. Butler, clinical clerk, is as follows:—

George C—, aged sixteen, a well-nourished youth, but of tubercular aspect (his mother being consumptive, and two of his maternal aunts having died of acute phthisis), was admitted on May 31st. Just a month before, he had been standing at a pier-head when heated from fast running, and in that way, as he supposed, caught cold. Shivering came on the next day, and he kept his bed for a fortnight, being "very ill"; the chief symptoms were coughing, with much expectoration, repeated nose-bleeding, and profuse sweating, especially at night. At the end of the fortnight the boy improved sufficiently to get up. He had lost much flesh during his illness, and his cough and sweating continued. As soon as he could bear the journey he came to hospital, where he was admitted at the date mentioned. When first seen the patient's aspect and pose indicated extreme depression, and there was that blush on his cheeks which, taken together with his lustrous eyes and long eyelashes, would suggest to the observer, other things being excluded, acute tuberculosis. The temperature was  $104^{\circ}2$  on the first night (for the next eight days the highest daily reading reached or exceeded  $104^{\circ}$ ). The tongue was furred; bowels confined. Pulse about 100. A very careful examination of the lungs discovered large rhonchi merely, no dulness; no small bubbling; no physical evidence of any kind, except of bronchial flux; the sputum bronchial and uncoloured. Such was his condition on admission, and so it continued for fourteen days; a condition, namely, of extreme depression, temperature ranging daily between  $102^{\circ}$  and  $104^{\circ}6$ ; absolute loss of appetite; sleeplessness, night-sweating, and wearing cough, with mucous expectoration, sometimes blood-streaked; the bowels being confined (except for one occasion, when they acted copiously after medicine), and the pulse seldom much exceeding 100. But what was the most striking and the most suggestive, or, as it seemed, probative of the diagnosis of tuberculosis, was that with the progress of time the patient rapidly wasted. That and the profuse sweating and prostration were the main features of the case, yet still with no more positive physical signs than those mentioned. Between the sixth and the twelfth days from admission the prostration was so extreme that it was only with great difficulty he could be raised, or indeed moved, for the purpose of examination. Yet, with an eye to possibilities, attention was continuously directed to the lungs, and it may be said positively that although bronchitis persisted, and

No. 3081.

some small bubbling was audible for a time at the left base, there was never any sign of consolidation or pneumonia. However, on the fourteenth day from admission (which would be six weeks from his first seizure and a month from the time when he had a temporary mend) signs of improvement were observed in that the night temperature fell from  $104^{\circ}$  to  $103^{\circ}$ , and the bodily weakness was less. From that day to the nineteenth a continuous progress began to open out hope of ultimate recovery. By the twenty-second day (making sixty-two days from the commencement of illness) that hope became almost assurance. The temperature had gradually fallen, and was now hardly above normal; the wasting and sweating had ceased; and, above all, the extreme bodily prostration had disappeared. With this marked improvement the catarrhal sounds within the lung underwent but little change, and on the twenty-eighth day, when he was up and convalescent, some bubbling rhonchus was audible at both bases. During the extremity of his illness it was impossible to take his weight; the only measure of the loss of flesh, therefore, is quite inadequate to express the fact. Before his illness he weighed 7 st. 10 lb.; on the twenty-seventh day after admission, and when approaching convalescence, he weighed 6 st. 8½ lb.; a week later he had gained exactly 4 lb. As regards treatment, all that it is necessary to say now is that on the 7th of June, when near his worst, and seven days before he began to mend, the boy was given ten grains of hypophosphite of soda every four hours, and this was continued for the rest of the acute illness.

In the main features of this remarkable case there are, as I think, to be found some important practical lessons—facts which are too little recognised and probabilities which are too easily set aside. Take first the fact itself. Better than all theories or precarious deductions is the knowledge which this case gives that in a tubercular subject a pyrexia of indefinite duration, which entails such wasting as almost to reach the point of emaciation, and is attended by profuse night sweats and extreme prostration, is a condition which may and which does recover. Let it be enteric fever or acute tuberculosis, or what you will, this combination of symptoms, grave as it is, as a rule fatal as it is, is not absolutely hopeless. That made certain, many other questions press for consideration. What are the probabilities in regard to diagnosis, and how are these affected by the fact of recovery? What are the particular circumstances of these recovering cases as to treatment? What is the likelihood that we may ever succeed in making recovery more common?

It has been said—the expression indeed is attributed to a very sagacious physician of our day—whenever you have to deal with pyrexia of anomalous character, the other symptoms not fitting in with any recognised pattern of disease, always put to yourself this question: "Have we here to deal with enteric fever?" But this admirable hint, so serviceable to prevent grievous errors, is not to be twisted from its real meaning. Some would put it not as a question to be deliberately decided yea or nay, but as an affirmation. Here is a pyrexia with anomalous symptoms. I cannot fit it to anything in particular; I will call it enteric fever, an affection which has so many forms that it may be fitted to anything.

Only just now, while I am speaking, we have an illustration at hand of the errors that may be committed and the valuable clinical knowledge that may be overlooked by such conduct as this. A patient in Burdett ward, with symptoms corresponding in many respects—in aspect, in temperature, in nervous prostration, in the colour and consistence of the motions—with enteric fever gets, too easily, credited with that disease. And if by any accident she had passed from our notice in the second or the third week of illness, her precise condition would take its place in our memory as a contribution towards the full conception of the many ill-defined modes of enteric fever. But it so happened that at the end of the fourth week she died, exhibiting post mortem, not enteric fever, or any trace of it, but the most characteristic and extensive ulcerative endocarditis.

In the case before us, however, there is not the same excuse as in the other—nay, the same necessity, we may almost say—for making use of enteric fever to eke out a doubtful diagnosis. Except for febrility, this youth had nothing of enteric fever about him either in his symptoms or in their duration. We put the question as we are advised, and we answer it without hesitation in the negative. Be it what it may, the disease we have before us is not enteric fever. Proceeding, as is the custom in such cases, upon the principle of exclusion, that alternative, at all

events, may be dismissed. But may we not go further, and say of this boy not only that his illness was *not* enteric fever, but that it *was* acute tuberculosis? Remember that while acute tuberculosis is very commonly mistaken for typhoid fever, the converse of this is not true. We have here the proper tubercular symptoms clearly marked out from the rest, symptoms which have been met with repeatedly in connexion with grey miliary granulations. There seems hardly room for mistake. Only when we are confidently expecting the boy's death, he disappoints that expectation and recovers.

Is then the fact of recovery to negative the diagnosis of acute tuberculosis? Of the actual deposit of tubercle it may indeed. No one, I suppose, believes that these little bodies may be thickly strewn throughout the lung in the way that we find them and the patient nevertheless recover. But there is much reason for believing that we may approach—who shall say how near?—to that pathological event and then stop short; just within the boundary, it may be, which separates extreme peril of death from the absolute certainty of it.

Did time serve I could adduce much evidence to prove that the condition we recognise clinically as acute tuberculosis is not necessarily fatal, whether occurring in youth and tending towards the lung (yet with no admixture of phthisis in the sense of lung destruction), or occurring in childhood and tending towards the pia mater. We get the very same group of symptoms in cases that are exceptional in that they recover, as in cases that form the rule in that they die; and, moreover, the earlier in life the observation is made—the nearer we get to that period when tuberculosis is seen, so to speak, in perfection,—the more does it appear that individuals may exhibit all the symptoms, not only premonitory of tuberculosis, but which are commonly believed to announce it, and then, when the diagnosis is complete and the prognosis seems certain, turn round and recover.

But I would ask you to look at the matter upon a somewhat broader ground. The recovery from tuberculosis, meaning by that term the clinical phenomena commonly supposed to be indicative of the deposition of miliary tubercle, so far from being rare, is a matter of frequent experience. What is rare, although less rare, I believe, than seems, owing in great measure to the habitual invocation of enteric fever, is its recovery when it has passed a certain stage. We all know and teach that children of a particular conformation, whose scalps sweat at night, who grind their teeth and but half close their eyes in sleep, and so forth, are especially prone to tubercle and to death by meningitis. We advise that particular care should be taken to preserve such children from cold, from foul dwellings, from overmental application; and we insist that the first signs of pyrexia or sickness, signs insignificant with other children, need immediate attention with them. Yet, in spite of all our precautions, or for the want of them, such children get pyrexia more often than others. A certain proportion—the most tubercular, if we may so speak—will inevitably die; the rest will die or not, according to the care that is taken of them, the food they get, and the place where they live. But hardly any, until the time of their special liability is over, will escape attacks in which they will be pyrexia and waste, and show symptoms, cerebral and other, which are often absolutely indistinguishable from those that usher in a fatal meningitis.

Still more striking is the case of young adults who are tubercular. With these we know that the chief danger is not for the brain, but for the lungs; and we have strong hope that if we can tide them over the period of youth later manhood will give them comparative security. But how is it with them during this time of jeopardy? Much more than with the little children, it is apparent that they will live or not, according as their circumstances are ordered; that their life depends, that is to say, upon the conditions of living being made the easiest for them. A young man of tubercular tendencies (I am quoting from the fact) wastes, and sweats, and coughs, but with nothing discoverable in his chest beyond bronchial catarrh. Soon he is too weak to leave his room. He is advised to take a sea voyage, and to remain for a year or more in New Zealand. There he loses his cough and his weakness, puts on flesh, takes to an active out-door life as a sheep farmer, and presently, as is but natural, pining for his home and his old profession, and believing himself perfectly recovered, he returns to England. Again there are the wasting, the cough, and the depression; and this time the symptoms are so threatening that

there is grave doubt whether he can be got on board ship, or whether in his extreme state a long journey is justifiable. But once more away from the country which is not liveable for him the threatening symptoms disappear, and his health returns.

Who then, I ask, will venture to say or to write in a book at what particular stage in the tubercular fever (so to call it) all expectation of recovery is cut off; or, rather let me say, not so much expectation as possibility? It would of course be a grotesque misrepresentation of nature to pretend that such a case as ours in Burdett ward is not highly exceptional; or that with such symptoms any other result than death is to be looked for. But who is to draw the line between recoverability and irrecoverability? who is to say what particular phase or event in the clinical history represents the actual development of tubercle and seals the doom of the patient? We have ample justification, I contend, in laying down as true this proposition: in youth as well as in childhood threatened tuberculosis recovers. We can tell when such recovery is to be looked for; we can tell when it is highly improbable; we can hardly tell, certainly we cannot tell precisely, the point at which it becomes absolutely impossible.

But there is another point for consideration. Tubercular individuals, children at all events, will present the clinical symptoms of tubercular meningitis, and die in the usual way, but post mortem neither tubercle nor inflammatory exudation will be discovered.<sup>1</sup> We have to reckon, then, with the following facts, and to make out of them the best hypothesis we can. There is a certain set of symptoms by means of which acute tuberculosis is commonly recognised at the bedside. Such symptoms commonly end fatally, and after death grey granulations are found in certain situations. But to this rule there are two kinds of exceptions. One where the symptoms in question do not end fatally; the other where, although ending fatally, no trace of the grey granulations is to be found.

What, then, is the hypothesis—I mean the working provisional hypothesis—which best fits this state of facts? I think it is this: Acute tuberculosis regarded from the clinical point of view is to be distinguished from the actual deposition of tubercle regarded as an anatomical fact. The early symptoms of acute tuberculosis are those which precede the actual development of the grey granulations. This latter event, analogous in some respects to the eruption of a specific fever, is preceded by certain phenomena extending over a variable period of time, during which restitution is still possible. And while, on the one hand, the deposition of tubercle marks the termination of hope, on the other the stress of the premonitory fever which precedes that occurrence may of itself suffice to produce death.

But here the therapeutist steps in, and clearly there is a place for him. If his experience be large, it will furnish him with examples which will easily push aside the assertion that the acute tuberculosis which seems to recover is in fact not what it seems, but enteric fever, or something else. He has, then, only to appeal to the dogma that acute tuberculosis, pursuing its natural course, is necessarily fatal in order to reach the position he desires—the doctrine, namely, that the cure of this disease is accomplished through the agency of the hypophosphites of lime and soda. My own practice with reference to such drugs is this. In the belief that they are at least harmless, that they are commended for a class of affections very bare of remedies, and where some medicinal treatment or other is reasonably expected on behalf of those who are acutely and progressively ill, I have uniformly given the hypophosphites in every case of acute phthisis or acute pulmonary tuberculosis that has been under my care for many years. Without being at all struck with the effects of a remedy very highly commended in some quarters, I can certainly quote instances where the hypophosphites have been so far injurious that patients have improved on their being discontinued. In the present case ten grains of the hypophosphite of soda were given every four hours, commencing a week after the patient's admission. His worst and weakest time, you will remember, was the week succeeding. How far this is consistent with any curative power of the hypophosphites I leave you to determine. For myself, I believe that when cases like this one of ours are more widely recognised; when the fact of recovery is admitted not only by

<sup>1</sup> As authority for this statement I might quote Dr. Austin Flint, Dr. Gee, and others. See a very suggestive paper by Mr. Howard Barrett, on Tubercular Meningitis, in the tenth volume of the St. George's Hospital Reports.

those who profess to have brought it about, but by others as well who are prepared to note all the circumstances under which it occurs,—when that time comes the curability of tuberculosis will be found to depend not upon the hypophosphites or any other preparation of pharmacy, but upon the employment of those agencies for its cure which are suggested by the causes that provoke it. Is there no therapeutical teaching in the fact that the tuberculous children of the poor develop tuberculosis as the rabbits do, by living in impure air and damp underground cellars; or the fact that a youth of tuberculous family will escape the fate of his brothers and sisters, and the fate that over and over again has threatened himself, by removing to some better country?

Those who are the most firmly persuaded of the incurability of acute tuberculosis will not deny that there are certain well-recognised signs by means of which the tuberculous are distinguished from the rest of the community; they will not deny that there are certain localities and certain modes of living the least hostile, each for each, to the lives of such persons, and that by having recourse to such places and plans the life that is repeatedly menaced during childhood, and youth may reach a healthy and secure manhood. But why need we stop here? I firmly believe that the time will come when what everybody admits will no longer be applied partially, but carried out to its full conclusion; and when it comes patients suffering like this boy whose case we have been discussing will be removed, wherever feasible, from their town surroundings, and placed without delay or fatigue in the best possible conditions for recovery upon some hill or mountain top, or, at all events, in the pure air of the country.

### ON THE INVISIBLE CORPUSCLES OF MAMMALIAN AND OVIPAROUS BLOOD, AND THEIR RELATION TO FIBRIN FORMATION AND COAGULATION.

By RICHARD NORRIS, M.D., F.R.S.E.,  
PROFESSOR OF PHYSIOLOGY, QUEEN'S COLLEGE, BIRMINGHAM.

In the *Bullettino della reale Accademia Medica di Roma*, Anno viii., No. v., pp. 174, *et seq.*, will be found a communication presented by Associate Colosanti on behalf of Professor F. Legge, which concerns itself with the controversy between Professor Bizzozero and myself. The communication is entitled, "Observations on the Blood of the Salamander and of the Triton, in relation to the plates (piastrine) of Bizzozero, and to the Invisible Corpuscles of Norris." The author first refers in the following terms to the original communication by Professor Bizzozero: "The distinguished Professor Giulio Bizzozero at the sitting of the 9th of December, 1881, communicated to the Royal Academy of Turin the discovery of a new morphological blood element to which he gave the name of 'blood-plate.'" The characteristics of this new element are that it is one-third or one-half smaller than the red corpuscles; that it has the form of a disc, or of a lens; and, finally, that it is colourless and excessively pale. This great discovery was made in the circulating blood, in which the plates are seen irregularly distributed among the red corpuscles. Bizzozero thinks that these little plates are to be regarded as special elements, since they are morphologically perfectly distinct, as much from the white corpuscles as from the red ones, and he thinks that from them originate those special accumulations of granulations to which modern histologists, and especially Ranvier, attribute the coagulation of the blood. If, in fact, the blood be observed outside the bloodvessels, without the addition of any reagent, the little blood-plates are seen to break up into exceedingly fine granulations, and at the same time is noticed the formation of a fine mesh-work, which is in direct relation to the above-named granulations. The presence of this network, which is composed of fibrous substance, points to the initiation of the blood-clot. Even the formation of thrombus and the coagulation of protoplasmic liquids, according to Bizzozero, is in connexion with the blood-plates. The same author has lately published that in the lower mammals the said plates are

nucleated, and correspond to those elements which Hayem has designated hæmatoblasts.<sup>1</sup> Subsequently, at a sitting of the Turin Academy, March 3rd, 1882, Professor Bizzozero states facts which, according to him, raise to a certainty the belief expressed that the blood-plates have, in relation to the formation of fibrin the function which Mantegazza and Schmidt attributed to the white corpuscles. This last fact was contested by Dr. Giulio Fano, in a note on the coagulation of the blood, published in vol. v., fasc. 4, of the "Archiv per le Scienze Mediche." In this note the author mentions facts which tend to demonstrate that, excluding the presence of the blood-plates, we can equally have coagulation in which, according to him, the white corpuscles take the most active part. He asserts, moreover, that upon the latter depends the coagulation in the lower vertebrata, since in them the blood-plates are completely absent. It will be observed that neither of these authors appears to consider that the blood-plates, or the white corpuscles, or the granules which they yield, are actually transmuted into fibrin, but only that they excite or determine its formation, and that the granules add to the bulk of the clot by becoming attached to the true fibrin, which is spoken of as being deposited in their vicinity.

Two leading considerations present themselves in connexion with these claims of Bizzozero—1. Is he the actual discoverer of the particular corpuscle in question? 2. Has this corpuscle the properties he ascribes to it, and if so was he the first to determine this? In the first place, these are visible delicately granular bodies, lenticular or disc-shaped, of smaller size than the red discs, colourless—that is, free from hæmoglobin, and nucleated. Now, here we have six very distinct characters, by which the corpuscles in question may be identified; and when we add to this the fact that they may be seen without difficulty, not only in the circulating blood, but also after it has been shed, it would certainly be a somewhat remarkable circumstance if they had altogether escaped the attention of the great army of microscopic observers of the blood. To the credit of physiology this is not the true state of the case. For several years past I have myself been acquainted with these particular corpuscles, and I presumed that other physiologists were also equally well informed. So far as I am able to understand the question, the confusion which exists appears to have entirely arisen from the too common practice of confounding together the leucocyte or white blood-corpuscle and the true lymph disc. In my first paper on the development of the blood<sup>2</sup> I pointed out that an able English investigator of the blood, Professor Gulliver, so far back as 1846, in his annotations to the collected works of William Hewson, strongly insisted that a distinction existed and ought to be recognised between the true lymph-corpuscles and the pale or white corpuscles of the blood, both as to their physical and chemical characters. He says, "The globules of the chyle, of the thymus fluid, and of lymph are smaller and differ in structure from the pale globules of the blood. In these last there are two, three, or four nuclei, easily seen when the envelope is made more or less transparent or invisible by acetic, sulphurous, citric, or tartaric acid. But the globules of chyle, of lymph, and of the thymus fluid, like the nuclei of the red corpuscles of the oviparous blood, are only rendered more distinct and slightly smaller by any of these acids, so that the central part presents no regular nuclei or divided nucleus, such as are contained in the pale globules of the blood. In short, these last-named globules have the characters of perfect elementary cells, while the former globules, as shown in the note to 'Gerber's Anatomy,' page 83, resemble, and probably are, nuclei or immature cells." Professor Gulliver also gave extensive tables of the measurements of red discs, of the pale corpuscles of the blood (leucocytes), and of lymph, chyle, and thymus corpuscles, under these distinctive headings, and pointed out that while the average diameter of the red disc in man was about  $\frac{1}{1000}$ , and that of the white corpuscle about  $\frac{1}{2000}$ , that of the true lymph corpuscle was only about  $\frac{1}{3000}$  of an inch, and that the latter was lenticular in form. He also made the additional statement, "In the blood besides the common pale cells (white corpuscles) there are a few smaller corpuscles, like those of lymph."<sup>3</sup> It is, too, a matter of history that the late Professor of Physiology in the University of Edinburgh, Dr. Hughes Bennett, did not, as so many have done, confound the white corpuscle (with which he was necessarily

<sup>1</sup> The oviparous hæmatoblasts of Hayem, not the mammalian, are here referred to.

<sup>2</sup> Birmingham Philosophical Society, 1878.

<sup>3</sup> Hewson's Works, pages 244 and 254.

so familiar) with the true lymph corpuscle, which latter element, as will be seen from the following quotations, he regarded as passing from a granular globular body, having a diameter of about  $\frac{1}{1000}$  of an inch, through the disc or flat stage, into the form of a colourless biconcave disc about the size of the red disc. After speaking of the molecular basis of the chyle, described by Gulliver, he says:—"Floating amongst these (oil globules) we observe globular and granular bodies about  $\frac{1}{1000}$  of an inch in diameter, which, on the addition of acetic acid, exhibit a thicker margin than they did before. In chyle taken from the thoracic duct there are also biconcave flattened discs, exactly resembling the coloured blood-corpuscles in size and form, but destitute of colour. Between these two kinds of corpuscles (the granular bodies, about  $\frac{1}{1000}$  of an inch in diameter, and the colourless biconcave discs) all kinds of intermediate stages may be observed, so that there can be little doubt that the former become flattened and are changed into the latter. They are, in fact, embryo blood-corpuscles, which become coloured in the lungs." Again, speaking of the lymphatic glands, he says, "On cutting into these glands shortly after digestion, and examining microscopically the fluid they contain, it may be seen that a molecular fluid (first described by Gulliver) is more or less crowded with naked nuclei, which resist the action of acetic acid. On repeating the observation on fluid taken from the thoracic duct the same thing is noticeable, only several of the nuclei are more flattened, and in every point, except colour, closely resemble the red blood-corpuscles."<sup>1</sup> Kölliker also recognised as the smaller chyle-corpuscles the bodies which I have called the primary lymph discs, and noticed also that their nucleated character disappeared, and that they became flattened. In my first paper on the development of the blood I have taken great pains to show that the so-called lymph globule is in reality a disc-shaped body, smaller than the blood disc, and that it consists of two varieties, to which I have given the names primary and advanced: the former being a true cell, the capsule or exterior of which is intimately applied to its nucleus, but which can easily be distended by osmosis, and its nucleated character revealed; the advanced lymph disc being, on the contrary, the delicate naked nucleus of this body, set free by disintegration of its capsule; both these bodies enter the blood, the former in health in small numbers only, and these remain visible, but become more delicate in appearance than they are when seen in the glands; this change appears to depend simply upon their transfer into the blood, for it may be effected artificially—that is, by adding gland discs to fresh blood.<sup>2</sup>

The advanced or nuclear lymph discs pass into the blood in far greater numbers, but for the most part being colourless and already smooth, enter at once upon their stage of existence as the invisible discs of the blood; a few of these, however, which are less perfectly elaborated, may remain for a time visible as finely granular discs. The former are the bodies which Professor Bizzozero has observed in the circulating blood of the lower mammals, in which they may be readily seen both while circulating and after the blood is shed. These bodies conform entirely to the description given by Professor Bizzozero, being visible, delicately granular in appearance, disc-shaped in form, of smaller size than the red discs, and colourless—i.e., free from hæmoglobin, and nucleated; and as there are in the blood no others in the least degree like them, it is logical to conclude that they are the bodies which he has observed. If this be so, although we may regard Professor Bizzozero as an independent observer of this particular corpuscle, we cannot admit his claim to the discovery of a new and previously unknown element of the blood. We come now to consider the rôle which this corpuscle plays in fibrin formation and the coagulation of the blood.

In February, 1878, I pointed out that there existed in the blood a series of corpuscles, the disintegrative changes of which were competent to account for and to explain all the phenomena of fibrin formation, and that the existing chemical views of coagulation must give place to morphological ones. I designated this series of corpuscles the "fugitive discs of the blood and lymph," in contradistinction to the more permanent corpuscles. I also photographed step by step the successive changes and variations in these bodies till they presented themselves in the well-recognised forms

of fibrin—e.g., films, networks, embolic masses, &c. Of this fugitive group of corpuscles some are visible, others barely visible, and large numbers wholly invisible. At both ends of the group there are visible discs, for it includes on the one hand the lymph discs which are antecedent to the invisible blood discs, and on the other those discs which have again become visible by the acquisition of colour, but which are not yet sufficiently stable to be included in the permanent group of red discs. These limitations I have repeatedly stated in my papers. That Bizzozero has been working on the lines I laid down in my papers to the Birmingham Philosophical Society in 1878 and 1880 will be sufficiently obvious to anyone who will take the trouble to read the preface of my work on the "Physiology and Pathology of the Blood," in which, to facilitate comparison, I have taken the liberty of placing our mutual statements in contrast side by side. It will be seen that the statements in respect to fibrin formation and the staining and preservation of the corpuscles concerned in it are essentially and almost verbally the same, and that mine possess the advantage of having been published for several years. My contention briefly stated is, that the red blood disc of the mammal begins its existence as the primary lymph disc, a body which is found in the spleen, in the lymphatic glands, in the thymus and thyroid, and in the bone-marrow. While in its own proper organs this body undergoes a development by which its nucleus is set free, this nucleus is transmitted to the blood, and becomes its smooth, colourless, invisible disc, which, taking on the biconcave form, gradually acquires colour, and becomes again visible in the blood as the palest order of coloured discs. Now the corpuscles concerned in fibrin formation in the blood are the lymph discs, the invisible discs, and the palest order of the coloured discs of the blood; to these, taken collectively, I have given the name of the "fugitive group." It will be remembered that I have divided the lymph discs into two varieties, the primary or nucleated, and the advanced, which is the liberated nucleus. As the corpuscles Bizzozero refers to were nucleated, it must be the former of these bodies; and if this be so, it is of the corpuscles of the "fugitive group," the one which is most permanent, and which therefore plays a smaller rôle in fibrin formation than the others. The bodies which take the greatest part in the formation of fibrin, both in the lymph and the blood, are simple nuclei; true fibrin, in fact, in all cases is formed of the material of which nuclei is composed.<sup>3</sup>

It is the advanced corpuscle, in other words the free nucleus of the lymph, which causes its coagulation, and it is this same body, when promoted to the dignity of a young blood disc, which causes the coagulation in shed blood. The few primary lymph discs (so-called blood-plates of Bizzozero) which are, as it were, accidentally present in the blood play but a very insignificant part in fibrin formation, very little, if any more, than the white corpuscles. I wish it to be distinctly understood that my views of the coagulation of the blood differ fundamentally from any which have hitherto been propounded; I desire to state them clearly and unmistakably, and then to abide the issue of time. The coagulation of the blood I believe to be purely a physical and morphological, and not a chemical, process; it is certainly a process every step of which can be traced by the microscope, and can be shown to depend on physical changes in bodies which were originally definite corpuscular elements of the blood, changes, occurring, in fact, in those corpuscles which I have included under the designation of the "fugitive group." These corpuscular changes are themselves sequential upon certain general alterations in the blood, when it is shed, as yet of an obscure character. Such a view of course excludes the idea that the liquid of the blood contains in solution the elements necessary to coagulation, and it equally excludes all such ideas as those of "ferment," "exciting or determining causes," "deposition of fibrin," &c. The study of the coagulation has unfortunately been conducted with pathological fluids which do not represent the normal state of things in the blood, but which are charged with products derived from the corpuscles. The pure liquid of the blood or lymph has no power to coagulate, nor does it contain those substances known as fibrinogen and fibrino-plastin, which are capable of being thrown down by solid salt and  $\text{CO}_2$  from the state of solution in pathological fluids. I make this statement advisedly, after the most careful inquiry, and with a full appreciation of the skimming

<sup>1</sup> Text-book of Physiology (Bennett), pp. 200 and 203.

<sup>2</sup> Physiology and Pathology of the Blood, pp. 116 and 127, published by Smith, Elder, & Co. 1882.

<sup>3</sup> The formation of fibrin by the invisible cell-bodies of the youngest blood-corpuscles of the ovipara is no exception to this rule.

experiments of Hewson and Hunter, the filtration experiments of Müller, and the subsidence experiments of Schmidt. These methods are all imperfect, because they fail to get rid of the morphological elements. Perfect filtration of the blood not only deprives it of the power to coagulate, but also shows that it does not hold in solution those substratal substances on the union of which coagulation is supposed to depend. When the blood is shed the corpuscles of the "fugitive group" are variously affected. The primary lymph discs (so-called plates of Bizzozero) granulate like the white corpuscles; the advanced lymph discs and the invisible discs tend to form sheets of fibrin by fusion and liquid subsidence; while the discs with a slight tinge of colour, apparently because they are more viscous and extensible, give rise to fibrinous networks. This much it is necessary for me to state in order that my views may neither be misunderstood nor misinterpreted. I will shortly expose my facts and experiments on coagulation in detail to the criticism of contemporary workers.

I desire now to refer briefly to that part of Professor Legge's memoir which is concerned with his own observations and experiments, and which he believes to have a direct bearing on the points at issue between Professor Bizzozero and myself. In publishing his investigations the author states he had two objects in view. 1. To determine if there be or not an identity between the blood-plates of Bizzozero and the corpuscles of Norris. 2. To determine if the same plates exist in the blood of the oviparous vertebrates. To this end he first examined the blood of the triton and salamander, as it circulates in the margin of the tail, in a part in which, in consequence of the narrowness of the capillaries, the corpuscles are moving slowly. He states that the morphological forms which present themselves under these conditions can be reduced to three: First, the red corpuscles; second, the white corpuscles; third, a special form of morphological element which differs as much from the red corpuscles as from the white ones. "This last one," he says, "although with some slight modifications, seems to me to have a very striking analogy with the plates of Bizzozero, since they, although like the red corpuscles, appear oval or fusiform according as they present themselves in front or edgewise, are smaller than these, strictly colourless, having no visible trace of hæmoglobin." "In the circulating blood," he continues, "it is not possible to decide if these are nucleated or not. It is only possible to observe that they are sometimes homogeneous and smooth, while at other times they are covered with small rounded prominences, which give them a mulberry-like appearance. Very striking is the distinction from the white corpuscles, a distinction observable as much in the form as in the manner of circulating, inasmuch as while the white corpuscles in the interior of the vessels here and there stop against the walls, and emit more or less numerous protoplasmic prolongations, or are seen to circulate in the form of round globules, the elements under consideration always maintain their oval form and circulate freely amongst the red corpuscles in the axis of the blood current, without ever stopping, unless they be compelled to do so by the extraordinary narrowness of the vessel. As to their numbers, these elements are rather more numerous than the white corpuscles, but are less numerous than the red ones; as a rule, one of them is seen for every forty or fifty red corpuscles; occasionally they can be observed in small groups of four or five together." The author then proceeds to examine the same blood immediately after it is shed, and says: "The above described elongated, oval, and colourless forms may be still observed; they do not, like the white corpuscles, exhibit any amoeboid movement, but show themselves with all the characters which individualise them in the circulating blood—i.e., their form remains elongated and oval, and their colour is like that of the white corpuscle, but a little paler. In form they are relatively more elongated and flattened than the red corpuscles; in construction homogeneous or slightly granular. Sometimes they contain a round nucleus, which, from unknown circumstances, is not always manifest. If we add methyl-violet to such blood the nuclei of the white and red corpuscles become rapidly coloured, but these elements do not become coloured, or only slowly, and with less intensity." The author then proceeds: "In addition to the above described elements, in smaller proportions, are observed corpuscles of an extreme pallor, and altogether homogeneous, which only reveal themselves by a line feebly refracting the light which surrounds them. In the interior

circle included in this line the corpuscle does not present traces of structure, and has the same index of refraction as the added liquid. Following for a long time one of these corpuscles, I have seen the said circle always growing paler, until it disappears altogether from observation. From the above-named facts we may deduce that in the blood of the triton and salamander are to be met, in addition to the white and red corpuscles, two other elements, of which one seems to be, although with some modifications, analogous to the blood-plates of Bizzozero, and the other to the invisible corpuscle of Norris. However, whilst the first must be held truly as a normal constituent part of the blood, of the other the same cannot be said, because only the first is found in the circulating blood, whereas the other is altogether absent. Nor can the objection be made of its excessive delicacy, because when we are forewarned it is possible to observe a detail, however delicate. I hold on the contrary, as asserted by Bizzozero in his note, in answer to Norris concerning the invisible corpuscle described by the latter in the blood of mammalia, and also for the form which I have seen in the blood drawn from salamanders and tritons, we must think of a product of change of the red corpuscles. When we examine blood with all due precautions, then the corpuscle in question does not appear at all in the preparation; but when, on the contrary, an ordinary preparation is made, then it appears in greater or less numbers; in fact, if, instead of examining the blood which escapes abundantly from the wound, we examine blood touching with the object glass a smaller wound of the skin, then the said corpuscles are excessively numerous, and that because in this manner the blood becomes mixed with the water which moistens the skin of the animal ..... making preparations of blood by adding common water, we have the same results, but the preparation remains more demonstrative, because all the red corpuscles undergo the same change. They commence to lose the hæmoglobin, becoming therefore little by little so pale that their cellular body disappears completely from view, a circular or elliptical line alone remaining visible."

The author concludes his memoir as follows:—

"1. In the blood of tritons and salamanders, in addition to the white and red corpuscles, is a special morphological element, which, if it be not identical with, is at least analogous to the blood-plates of Bizzozero.

"2. In the preparations of the said blood are observed colourless discs which correspond to the description which Norris gives of his invisible corpuscles.

"3. These discs are the result of an alteration which the red corpuscles have undergone in the presence of water."

(To be concluded.)

## ON SOME DEFORMITIES OF THE BODY INCIDENT TO THE PERIOD OF GIRLHOOD.

By CHAS ROBERTS, F.R.C.S.,

LATE ASSISTANT-SURGEON TO THE VICTORIA HOSPITAL FOR SICK  
CHILDREN, ETC.

I HOPE the time is not distant when a careful study of the living model of the child and the adult, and the whole period of the development of the one into the other, will form a part of the student's ordinary course of anatomy and physiology, as such knowledge is essential to the surgeon engaged in removing and preventing deformities of the body. Orthopædic surgery as a specialty is a great evil both to the profession and the public. The specialist who concentrates all his attention on a narrow field of study and practice is tempted to exaggerate its importance, and to analyse and disintegrate his facts till he loses sight of their relation to, and their dependence on, each other; while, on the other hand, the general practitioner is disheartened and repelled by the apparent complication of the subject, and is induced to hand over to the specialist many cases which he is quite competent to treat, or, as is too often the case, to undervalue the importance or deny the existence of many deformities. How else can we explain the difference in practice between the fussy mechanical ingenuity with which many professed orthopædists treat the slightest deformities of children—

which, by the way, they often tell us are only visible to their specially trained eye, and are hidden from that of the family doctor,—and the *sangfroid* of the general practitioner who meets the difficulties by the administration of a few doses of steel and quinine and rest in the recumbent position?

No deformity of a child's body gives rise to so much alarm to parents, or is the subject of greater diversity of treatment among medical men, as lateral curvature of the spine, and this is due, I believe, to an imperfect acquaintance with its origin. Specialists are accustomed to treat lateral curvature, knock-knee, and flat-foot as distinct deformities, while in truth they are all links in the chain of one deformity. Lateral curvature may arise in different ways, but in all cases it is due to the loss of the lateral balance of the body in the upright position, and is the result of an effort of nature to maintain the centre of gravity of the body and support the head and shoulders in the position which requires the least expenditure of muscular effort. The paralysis, wasting or loss of a limb, or the shortening of one of the legs by disease of joint, rickets, knock-knee, or flat-foot in growing children, will produce lateral curvature, and these are its chief if not its only causes. It is not a deformity arising from general debility, and I do not think it can be produced, as is often asserted, by an awkward sitting position, as in writing and other school occupations. The curvature of the spine which results from these causes is antero-posterior, or what is commonly called round-shoulder (non-carious). The tendency of debility, whether local or general, is to bring the body into the prone or recumbent position, and not to tilt it on one side.

Setting aside the cases of lateral curvature in children who have been affected with rickets, disease of joints, paralysis or loss of a limb in early life, and which affect both sexes, and all ages equally, what may be called the idiopathic or acquired deformity is rarely found in children of either sex under the age of nine or ten years, and very rarely in boys above that age. It is, indeed, almost peculiar to girls verging on puberty, and is as often found in strong and healthy as in weak and delicately built girls, and most commonly in those who are too fat and heavy for their stature and age. It is a deformity which is less common among the labouring classes than among the rich and well-to-do, and is largely associated with a life of indolence and luxury.

A careful examination of the subject has satisfied me that this acquired lateral curvature in girls is due to the change in the position of the lower limbs resulting from the development of the pelvis from the infantile to the female type a year or two before the accession of puberty. Anyone who will examine the figures of young children below this age will find little differences between the two sexes. The legs of young girls are set on the body like those of boys, and, within the limits of their training and dress, they can run as well and as gracefully as boys; but as puberty approaches and the pelvis alters its shape, the heads of the femora are removed further from the centre of gravity, and at the same time become rotated forward by the widening of the pelvis, and especially of the outlet of the pelvis. The effect of these changes is to bring the knees closer together, and produce the weak-kneed condition and the awkward running gait peculiar to women. This condition of the limbs is well seen in pictures and statues of the nude figure, and it is often exaggerated by the artist or sculptor, probably to give a more distinct idea of a woman's helplessness or modesty. The knee-cap in women looks straight forward, while in men it is turned a little outward; and in women the knees touch, or even overlap each other, while in men they are quite free. In running, a woman has to move the knees round each other, and to throw the feet out in a succession of small semicircles, which accounts for the peculiarity in her gait. This gait is not found in young girls before the onset of puberty, and is useful as a diagnostic sign of pelvic evolution long before the ordinary signs appear.

Although this weak-kneed condition is quite normal, it is a fruitful source of deformity in growing girls. A little additional strain will convert it into knock-knee, and by throwing the weight of the body on the inner ankle, it will quickly break down the arch of the foot and produce flat-foot or complete eversion of one or both feet. It is here, indeed, that nearly all the mischief lies, for according to my experience ninety per cent. of the cases of lateral curvature of the spine in girls are associated with flat-foot. This deformity is exceedingly common among women, and a French *savant* recently quoted it as a proof of the physical inferiority of woman to

man. To a slight extent flat-foot may exist in all women, as the position of the lower limbs after puberty would seem to produce it, and it may be nature's plan to promote what anthropologists call marriage by capture; but to a large extent, and in its worst forms, flat-foot is the result of civilisation. Indeed, both the highly arched instep and the everted foot are peculiar to civilised peoples, and are absent from the lower races, especially those who go barefoot, and both conditions owe their existence to the wasting of the muscles which flex the toes and foot by the constant use of tight-fitting shoes. In India, where the native workman makes use of his toes with almost the same facility as his fingers, the instep is obliterated by the fleshy bellies of the abductor of the great toe and the short flexor of the toes, which stretch across the arch from their attachment to the heel bone. The wasting of these muscles is of little importance to us who have no need to use our toes in detail; but it is far otherwise with the deep flexors of the foot and toes which are attached to the leg bones, and whose tendons pass under the ankle-joint and arch of the foot and form their chief support. It is, indeed, from the wasting or inaction of the deep flexor muscles, coupled with the turning out of the toes which fashion has imposed upon us, that the ankle and arch of the foot give way under the changed position of the

The diagram shows the relation of the brim of the pelvis in the child, at puberty, and in the adult female, from measurements of pelvis in the museum of the Royal College of Surgeons. The want of parallelism of the two inner pelvic curves shows that in the change from the infantile to the female type evolution takes place chiefly behind, and that the legs must be rotated forwards and inwards. The dimensions are:—Child: breadth 83 mm.; length 73; index 114. Young female: breadth 112 mm.; length 85; index 132. Adult female: breadth 143 mm.; length 108; index 132. The indices of the young female and the adult are the same, but the bones of the former are not united together.

limbs in girls at puberty, which I have described; and what is remarkable, and not easily explained, the deformity generally occurs only in one foot, or is greater in one than the other. In this way, however, the legs become of unequal length, and we have obliquity of the pelvis, and consequently, lateral curvature of the spine to correct the balance of the body, and bring the head and shoulders into the line of the centre of gravity. Flat-foot also produces, or exaggerates, the natural disposition to knock-knee in girls, which, in its turn, adds to the inequality in the length of the two legs. Some observations recently made in America show that even in adults of both sexes the two legs are rarely of equal length, and there must be, therefore, slight lateral curvature in all persons, and it is probable that these natural curves become exaggerated, as in the development of round shoulder the large antero-posterior curves of the spine are exaggerated. It is to the wasting or non-development of the fleshy parts of the deep flexors of the toes or foot that Europeans owe the small ankle and the comparatively large calf of which they are so proud as distinguishing them from the lower races. It is a distinction, however, which is more than counterbalanced by the ugliness and inconvenience of flat-foot, to which it frequently gives rise. The ingenuity of an Edison could not devise a machine so favourable to the production of flat-foot as the tight-fitting, high-heeled, long-topped boot at present worn by girls. Not only does the rigidity of the front part cramp the action of the muscles, but the high heels place the foot at such an angle with the leg that the tendons are of least use in supporting the ankle-joint, and the long tops hamper the development of the muscles in the remainder of their course. The

high heels, moreover, push the centre of gravity forward on the arch of the foot, and by propping up the heel gives greater leverage, and a greater space for the arch to fall when once it gives way. In the majority of cases the mischief would stop when the arch reached the level of the natural heel, but the heels of boots favour a still greater fall, which ends in eversion of the foot. It is difficult to understand how women submit to the discomfort of wearing high-heeled boots, or can be so cruel as to let their daughters wear them. It is true they give a fictitious height to the body, and disguise the slighter forms of flat-foot, but on the other hand they exaggerate the severer forms, and the boots are entirely wanting in proportion. Zeising's law of proportion requires that the sole and the heel should have the relative length of three to two, like that of the normal foot.

In treating the deformities of the spine and legs incident to healthy girls, it is obvious that attention must be directed in the first instance to correcting the deformed knees and feet. The very first signs of the giving way of the arch of the foot, which is easily detected by examination, by growing pains, and especially a change of gait, should be met by the wearing of flat-soled, well-fitting boots, with indiarubber or felt pads inside to support the arch, and special exercises favourable to the development of the deep flexor muscles. At puberty, and for two or three years before, the growth is very vigorous, and in both stature and bulk girls shoot ahead of boys of the same age, the period of rapid growth of boys coming later. From ten to fourteen years the stature of girls increases at a uniform rate of two inches per year, except at thirteen, when it is two inches and a half, but the weight increases at a much greater rate. At ten years girls add 4 lb., at eleven 6 lb., at twelve 10 lb., at thirteen 12 lb., and at fourteen and fifteen 8 lb. to their weight, and this sudden addition to the weight tells rapidly on ankles, feet, and knees placed at a disadvantage by concurrent change in the position of the lower limbs by the evolution of the pelvis and the cramping of the muscles by tight boots. The arch of the foot often breaks down in the course of a few weeks, without warning or apparent cause, and in girls in perfect health, and especially those of an indolent habit. Fortunately the remedy is as easy and complete if applied promptly at the beginning and adhered to persistently, as it is difficult and unsatisfactory if put off till the deformity is firmly established. Support to the arch of the foot prevents the formation of knock-knee and lateral curvature of the spine. When it fails to do so, the knock-knee can be corrected by the temporary application of long splints, especially in bed at nights; but no apparatus is necessary for the curvature of the spine in its earlier stages, as it will disappear on restoring the lateral balance of the body, and all treatment will be useless until this is done. Much walking or standing should be avoided, and short but vigorous gymnastic exercises substituted, and when possible the recumbent position assumed. Sitting on the ground or on a sofa in the cross-legged oriental position serves to expand the pelvis, evert the knees and invert the ankles, and counteract all the deformities; while sitting on chairs with the legs crossed one over the other directly favours them. It is probable that most children spend too much of their time on their feet, and that their powers of walking is very much overrated. Running is the natural gait of all young animals, and children always run if left to play by themselves. The dire effect of standing and walking in producing flat-foot in children is shown by the following statistics, taken from my paper on "Flat-foot" in the St. George's Hospital Reports (1872-4): Of 10,000 children between the ages of eight and thirteen years which were examined, about one-third were school children living in country towns and agricultural districts, another third were school children living in manufacturing towns, and the remainder were factory children. Among the first, 17.1 cases per 1000 of flat-foot occurred; among the second, 30.7 cases per 1000; and among the third—i.e., the factory children, who were employed five hours' daily standing, walking, and carrying weights—79 cases per 1000 of flat feet were found. Among the latter the deformity was found to increase rapidly with age—i.e., with the longer period of employment in factories. Thus:—

Of the age of 8 years, 15.1 per 1000 had flat-foot.

9	45.6	"	"
10	51.2	"	"
11	104.2	"	"
12	132.4	"	"

At the period when these observations were made (1873) children were allowed to commence work in factories at the

age of eight years, instead of ten as now, and the low rate of 15.1 per 1000 represents the normal rate before the strain of labour has begun to tell on the children's feet.

There can be little doubt that children are made to stand and walk far too much both at home and at school. Standing at lessons, parade exercise, and much of the military drill in schools are injurious to both boys and girls, and especially to the latter. Instead of listless standing about, or taking long walks with adults, children should be permitted and encouraged to play lively games, which they will generally do even if left to themselves, to dance, and to perform short but spirited gymnastic exercises with apparatus. Exercises which develop the muscles of the feet and ankles, such as hopping and skipping, are especially necessary for girls; and still better than these are the admirable exercises preparatory to stage dancing taught at the National Training School for Dancing.<sup>1</sup> These exercises are directed to the development of the muscles and the free action of the joints of the lower limbs, and are far preferable to the languid movements of ordinary dancing. For the development of the muscles of the trunk and arms the excellent system of gymnastics for girls recently established by a lady<sup>2</sup> in various parts of London, with the approval, after careful and repeated inspection by myself, of Dr. Richardson, Mrs. Garret Anderson, and others, is all that can be desired. The Swedish and other exercises effected without apparatus are of little use, as idle and indolent girls who stand most in need of physical training easily comply with the form, but evade the spirit and hearty compliance which such systems demand. These systems lack motive to complete an exercise, while simple apparatus such as balls, dumb-bells, and bars compel it by keeping the end in view and giving an impetus to its performance. With half the care which mothers spend on dressing and decking-out their children, often in unsuitable clothing, they might, with a little help from their medical advisers, prevent most of the deformities which mar the physical beauty, comfort, and health of their offspring; and no time seems more appropriate than the present for directing the attention of medical practitioners, and through them of parents, to the means of attaining these objects, as the short walking dresses worn by women and girls at the present time reveal to all of us to what a great, indeed unexpected, extent the ugly deformities of the feet and ankles to which I have referred exist, especially among the well-to-do and higher classes.

## THE PATHOLOGY OF HEPATIC TUMOURS.

By WM. ROBT. SMITH, M.D., F.R.S. Ed.

(Continued from p. 384, vol. i., 1881.)

### MALIGNANT GROWTHS, WITH MICROSCOPICAL DEMONSTRATIONS.

(a) *Cancer*.—Cancer is found in the liver either as a primary growth or secondary to cancer elsewhere. For many years it was taught the primary variety was the most frequent, but now it is known that more than three-fourths of all cancerous growths in the liver are of metastatic origin, and of these metastatic deposits by far the larger number are secondary to primary cancer arising somewhere within the portal area.

There are two forms under which we meet with primary hepatic cancer—viz., first as a large solitary rounded tumour, and secondly as a diffuse degeneration of the entire organ, the liver meanwhile retaining its normal shape. When present as a solitary tumour, the growth is round and frequently of enormous size. Sooner or later it projects above the surface as an irregular prominence, over which the capsule becomes thickened and opaque. On section it appears as a soft pulpy growth of a greyish colour, from which a thick cream-like liquid exudes on pressure. It is seen to be traversed by glistening fibres varying in thickness; they have a reticulated arrangement, which gives the cut surface a lobulated appearance. In many places the external border is sharply defined, whilst in others the borderline between hepatic tissue on the one hand and cancerous growth on the other is indistinct or altogether wanting. As we should expect, the hepatic tissue and bile-ducts in the

<sup>1</sup> Under the direction of Madame Katti Lanten.

<sup>2</sup> Miss M. A. Chreiman, 69, Petherton-road, N.

neighbourhood are distinctly compressed, whilst some of the larger ducts are found blocked with cancerous masses; the portal and hepatic veins also contain cancerous thrombi, and are dilated. The mass may present certain varieties of retrogression—e.g., its centre may become converted into a dry yellowish cheese-like substance, owing to fatty changes in the cancer cells, or extravasations of blood show themselves as hæmorrhagic infarcts, which ultimately break down into dry hard masses, and, owing to the compression of the bile-ducts, the flow of bile is impeded and the organ becomes of a yellowish or greenish hue.

The diffuse or infiltrated variety of primary cancer is but rarely met with, but when observed is found to have a highly characteristic form. The liver is enlarged in all directions, the capsule thickened, and the surface covered with slight rounded elevations varying in size from that of a pea to a small nut. On section the lobules are seen to be enlarged, although their shape and outline are still preserved; but they are more or less transformed into cancerous matter. They are separated from each other by broad tendinous bands of fibrous tissue; they are either whitish in colour or yellow or green from the inhibition of bile, and are decidedly more succulent and pulpy than the ordinary hepatic tissue. The fibrous interlobular septa, owing to their vascularity, may have a tint varying from pink to bright red, which gives the organ a brilliant appearance. This variety of cancer, unlike the one just described, either undergoes no retrogressive change, or but slight fatty degeneration of its cells; the portal and hepatic veins and the bile-ducts are unaffected; whilst, as is also the case with the solitary growth, metastases to distant organs never occur, although the lymphatic glands found in the transverse fissure may in both cases be affected.

Microscopically, primary cancer presents the ordinary features of a medullary growth. It consists of large, round alveoli, the walls of which are composed of fibrous tissue and capillary bloodvessels, these latter being sometimes alone present. The alveoli are filled with cells which may have no particular shape or arrangement, at other times being cylindrical and symmetrically arranged. The capillaries derive their blood from the hepatic artery. These cancer cells are no doubt the direct offspring of the hepatic cells, although by some the epithelial cells of the smaller bile ducts are supposed to contribute in their formation. In both forms of the primary growth the cancerous transformation of the hepatic cells is the same, and may be studied in the various sections I have placed under the microscope. The true hepatic cells at first enlarge, by which the rows of cells become distinctly widened and separated from each other; at the same time the outline of the cells becomes very indistinct or altogether lost; the lobules then appear to be transformed into a number of protoplasmic masses, with a corresponding number of nuclei; these nuclei rapidly increase in number by the process of fission. This transformation of the hepatic cells is confined to a limited number of the rows of cells; the remainder, together with the capillaries, undergo atrophy from pressure; the portal capillaries, thus compressed together, with the connective tissue surrounding them, form the fibrous stroma of the growth; the capillaries which nourish the tumour are branches of the hepatic artery which have sprung into existence with the growth of the mass. It is, however, as a secondary metastatic growth that we have most frequently to deal with in cancer of the liver, the infecting source being generally the pyloric end of the stomach; it may likewise proceed from cancer of the intestines or peritoneum. If we reflect on the origin and distribution of the portal vein and lymphatics, we can readily understand with what ease the cancer germs may be transported. Secondary cancer of the liver appears nearly always as a number of deposits or nodes, and with extreme rarity as an infiltration.

The external appearance of a cancerous liver varies greatly. A number of milk-white nodules may protrude on the surface, which, on section, are found to vary in size from a millet seed to that of an orange, and to be sparingly scattered through a more or less atrophied parenchyma; or, on the other hand, the liver may be enormously enlarged, presenting superficially a number of umbilicated or centrally depressed nodules, being very much like a *nux vomica* seed, and about the size of an orange. The secondary hepatic growth increases so rapidly in size, and reveals to such a great extent retrogressive changes, that the primary infecting source is in danger of being overlooked, for very frequently the primary growth causes no very marked symptoms, and

unless systematically looked for the actual site of origin of the lesion is often overlooked, for the secondary growth of the liver is so large that it readily obscures the primary and insignificant one of the pylorus. About five-sixths of all cancerous growths in the liver have a metastatic origin, and of these two-thirds are secondary to primary cancer in the portal area, and one-third to primary cancer elsewhere, being very rarely metastatic to cancer of the skin. There can be no doubt that these growths are due to the presence of cancerous emboli in the branches of the portal vein or hepatic artery. The nodes which are seen on section scattered throughout the liver substance vary much in number, size, and general character; they may be so small in size and so limited in number that they may escape suspicion during life, and be only accidentally discovered at the post-mortem. Generally, however, they are scattered irregularly throughout the organ, in numbers varying from two or three to fifty or sixty, or more, at the same time presenting the greatest differences both in size and shape—the size varying from minute granules imperceptible to the naked eye to that of an orange or cricket-ball, the average size being that of an egg or an orange, whilst the usual shape is globular. They are sharply circumscribed, but not encapsulated, and they cannot be easily detached from the liver substance, which is in immediate contact with their borders, although neither compressed nor altered in character. These nodes increase in size in one of two ways: they grow at their margins by progressively invading the healthy tissue, or they coalesce with smaller nodules in the immediate neighbourhood, but at the same time the central portions fall into a more or less rapid degeneration of the fatty, caseous, or calcareous variety, which is the cause of the characteristic cupping. In the unaffected parts of the liver there is usually great hyperæmia, which doubtless has something to do with the enormous enlargement of the organ which so commonly takes place; often, too, the liver appears intensely yellow from retention of bile in consequence of compression of the biliary ducts, but it is important to note that the liver substance seldom exhibits signs of compression, the foreign growth apparently taking the place of the normal tissue.

If we examine these nodes a little more closely we shall find that in all their essential details the characteristics of the infecting growths are repeated. On the surface they are usually of the scirrhous variety, more internally they are of the medullary type, a creamy juice exudes from the cut surface in variable quantity, which microscopically exhibits the ordinary appearances. On the surface we have already noticed that the growths rise at their edges, and if we trace them downwards we shall find them to be rounded masses lying in the liver substance, having stellate bands of fibrous tissue radiating out from it towards the surface. It is the contraction of these bands which causes the characteristic umbilication. A number of small yellow spots are visible in most growths which correspond to parts undergoing fatty degeneration. These retrogressive changes arise most rapidly in parts removed from the source of nutrition, which is at the periphery of the nodule; the centre, therefore, is most prone to be affected, the cells, of which the growth in great measure consists, undergoing fatty changes and resorption. The stroma may also participate in the degeneration. The absorption occurs only when the nodule is superficial, when the side towards the peritoneum can sink in and give rise to the phenomenon of umbilication. At this stage, if the growth be cut into, we find nothing but the cicatrix left after the removal of the cells. When the nodule is more deeply situated and surrounded on all sides by a stratum of uniform thickness and rigidity, cancerous abscesses are formed as a result of the degeneration (*Geschwulstwand*).

Another form of degeneration which these growths, more particularly the larger ones, undergo, is the cheesy variety. The cancer masses in this case become dry and hard, and the cut surface appears of a yellowish-grey tint; the cells and stroma both participate in the process; the vessels are destroyed; the whole mass being ultimately transformed into a finely granular detritus.

In the earliest stages of the disease the liver is seldom increased in size, or altered in form, although it contains a large number of cancer nodules of small size; however, as these become more numerous, and especially as they increase in size, the organ undergoes great alterations in shape, volume, and weight, becoming enlarged, much thickened, and enormously increased in weight; indeed, sometimes the liver weighs from 20 lb. to 25 lb. in such cases. On section

very little of the normal parenchyma is found to remain, which as a rule shows no morbid change or sign of compression; the branches of the portal vein are often found filled with cancerous emboli; they lose themselves in the nodules, thus rendering it very difficult to say with certainty whether the nodule is the result of the emboli found in the vessels, or whether the diseased condition of the vein is itself secondary to the cancer growth, unless indeed the small branches of the portal vein containing emboli are continuous with the gastric and portal veins arising in the vicinity of a cancerous growth of the pylorus, and they themselves contain emboli of a malignant character. The walls of the gall-bladder and the lymphatic glands lying in the portal fissure are likewise affected with cancer.

(To be concluded.)

## SOME UNCOMMON SEQUELÆ OF DISEASES OF THE SKIN.

By W. ALLAN JAMIESON, M.D., F.R.C.P.,

LECTURER ON DISEASES OF THE SKIN, EDINBURGH SCHOOL OF MEDICINE.

CUTANEOUS diseases, while presenting in general a somewhat uniform course as regards each particular disorder, exhibit at times certain peculiarities which may be due to the individual or to the locality affected, or to some special modifying circumstances. They are, however, also subject to sequelæ which may be regarded as rare. And to instances of these I wish to direct attention.

**CASE 1. *Urticaria following Scabies in an Adult.***—A fresh-coloured healthy young man of twenty, who in the course of business had to travel much and sleep night after night in beds sometimes not of the cleanest, consulted me about an itchy eruption which had annoyed him for a couple of months. It began about the wrists, then spread to the thighs, arms, and shoulders. The lesions consisted chiefly of scratched papules and isolated vesicles. There was scarcely any irritation in the daytime, but it became most annoying when warm in bed at night. A brother who lived with him was similarly affected, and a physician in France whom he had consulted told him he had "gale." I ordered a warm bath and an ointment containing storax and balsam of Peru. Two months after he came back, and informed me that the eruption for which he had asked my advice had long disappeared, but ever since he had been troubled with a prickling and itching sensation, accompanied with the development of very evanescent wheals. These chiefly appeared on the thighs, where the scabies had been worst, and only when warm and in bed. There was nothing visible when I examined him, but he said a warm bath would immediately evoke them. He was directed to sleep lightly covered at night, to avoid warm baths or any stimulants to the skin, and to sponge the body before retiring at night with a lotion containing carbolic and prussic acids, spirit of camphor, and a little glycerine. I heard no more of him, so I assume this relieved him.

Mr. Hutchinson has made us familiar with the various itchy eruptions which children are liable to as a sequence of the bites of insects, of scabies, and of varicella; but it is seldom irritation of such persistence follows scabies in a healthy adult, more particularly when an ointment so slightly irritating is employed for the destruction of the acarus. The following may be regarded either as an accident of the eruption or as a consequence of it.

**CASE 2. *Enlargement of the Inguinal Glands following Zoster Abdominalis.***—A young man of a rather lymphatic temperament, engaged as a law clerk, consulted me about a painful swelling in his left groin. The inguinal glands were found to be much swollen, tender, and painful. There was no gonorrhœa or chancre or history of either, but on examining the flank a group of vesicles on a hyperæmic base was found just above the crest of the ilium, and another nearer the spine and higher up. His bowels were habitually constive, and he accounted for the glandular enlargement by straining at stool; the presence of the patches of herpes zoster afforded, however, a much more rational explanation. He was directed to paint the patches of vesicles with flexible collodion, and to take some compound liquorice powder as an aperient. I have not observed any notice of glandular enlargement as a sequence of the eruption of zoster, and

cannot recall a case in which any complaint was made of it. Such an occurrence would seem therefore to be rare, while the situation would without further examination have raised, as it did to me at first, a suspicion of gonorrhœa. When one considers how much inflammation in the skin is sometimes produced in zoster, it is certainly rather surprising that sympathetic adenitis does not happen often.

**CASE 3. *Keloid after one Erasion with the Sharp Spoon.***—About a year ago Mr. Chiene asked me to see with him a young female, aged twenty-six, who had a curious black mark on her shoulder, just above the spine of the right scapula. This spot had existed as long as she could remember. When ten years old it was, she said, about the size of a threepenny piece. Of late it had grown larger, and had reached the size of half a crown. At its upper part it was of a deep bluish-black, and well defined from the surrounding skin. At the lower part was an outlying ring, reddish-brown in tint; and between these limits was an area little altered from normal in hue. Though apparently not elevated above the surface, when the fingers were passed over it little shot-like bodies could be felt rolling beneath them. The affection was quite superficial, and involved little more than the rete mucosum. The cuticle over it was shiny, thin, and as if loosely attached, and was wrinkled vertically in fine lines. It itched at times, and was painful when dragged but not when pressed. The patient is stoutish, with a fair skin, has had slight hæmoptysis, and suffers from bronchitis every winter. She is easily fatigued. Bowels rather constipated. Menses regular, but scanty. I attacked the growth with the sharp spoon, and though the resistance was considerable most of the mark was removed, some pigment which obstinately refused to be separated still remaining. The part was then dressed with absorbent cotton, and afterwards, till healed, with boracic lint and lotion. Professor D. J. Hamilton examined the scraping for me, and found it was a blood-clot under the epidermis. So perfectly had the encysted blood been preserved that the cells were distinct, and probably because they had not broken down had consequently not undergone absorption. More than six months after she came back, and on looking at the part which had been scraped I found that a nodule of keloid had become developed in it. It was about one-third of an inch in diameter, of a square shape, and reddish-pink in colour. It was both rather tender to touch and smarted a little spontaneously. I directed it to be painted with a solution of iodoform in flexible collodion, but this a couple of months after had done no good. It was quite unchanged. Erasion when employed for the removal of a new growth, such as lupus or epithelioma, seems to have no tendency to occasion that disease of scars which we know as keloid. Here, however, there was no new formation, and it may have acted as repeated multiple scarification has been found to do in nævus, and set up an irritation in the corium which eventually took the form of keloid. The singular point is that only one erasion was done, and yet keloid grew in the cicatrix.

**CASE 4. *Pruriginous Eruption as a Sequela of Psoriasis, and possibly Scabies also.***—A healthy-looking man, about thirty-six years of age, consulted me in March last. He had then well-marked patches of psoriasis on his back, abdomen, arms, legs, and head. These bore few scales, as he had been taking arsenic. Though he has suffered from the disease for some time, it went nearly entirely away last summer and winter, to return this spring. The psoriasis itself was more than usually itchy, but, besides this, there were small and discrete papules on the flexor aspect of the wrist, and a vesico-pustular eruption on the penis. These parts were specially irritable at night. On the head, great part of which was bald, the spots of psoriasis were erythematous maculæ, and not itchy. He was directed to take a warm bath, and then apply an ointment of storax and balsam of Peru to the body, and one of rufigallic acid (one in ten) to the head. One-fiftieth of a grain of arsenious acid in pill was prescribed to be taken three times a day. The itching was relieved, but not cured by the use of the storax ointment, and the arsenic was gradually increased to the one-twentieth of a grain thrice a day. At the end of April he went to a hydropathic establishment, where he continued to improve as regarded his psoriasis. When seen in the middle of July the psoriasis had disappeared, but the skin of his hands was uniformly rough and dry. Inside the thumbs and between the thumbs and forefinger, as well as between the fingers themselves and on the knuckles, the surface was warty in character, not unlike the veruca necrogenica of Wilks. Over the whole of the arms, trunk,

abdomen, and back were deep crimson-red papules, intensely itchy, and many of them torn and scratched. Though most of these papules were seated at hair-follicles, they had neither the appearance nor the arrangement of those of lichen ruber. They were not set in lines nor aggregated into patches, nor had they the peculiar horny glance which characterises those of lichen. While very itchy at night, they gave comparatively little annoyance in the daytime, but his rest was broken and his life rendered miserable. His appetite had not failed, though he felt somewhat languid, and unable for prolonged exertion. I ordered him a nightly bath at a temperature of 90°, containing two ounces of sulphide of potassium in each bath; and after the bath to be painted with a lotion containing carbolic acid and glycerine; for the hands inunction with glycerine of starch, and twenty drops of tincture of gelsemium as an antipruritic at bedtime. A week afterwards he wrote to me saying that he was much relieved. He could now sleep the greater part of the night with comfort. He found the lotion cooling and pleasant, and his hands were softer, and the skin more pliant. I recommended continuance of the same treatment, simply adding some spirit of camphor to the lotion. Ten days more elapsed, and then he wrote to me that his hands were nearly well, and except his arms, which still rather rebelled, his body also was almost cured. I permitted the discontinuance of the sulphur bath in the meantime, the resumption of the morning cold tub, with inunction with glycerine of starch afterwards. I have not since heard from him.

Poriasis seldom itself itches much when uncomplicated; and a pruriginous eruption like this developing out of it must be regarded as uncommon. In some respects it seems analogous to what Dr. Tilbury Fox described as pityriasis pilaris, which occasionally follows pityriasis rubra. But the colour constitutes a difference. The influence sulphur baths had in allaying the itching would seem to bring it into relation with Hebra's prurigo; and, indeed, the general aspect of the eruption resembles nothing so much as the plate of prurigo in Fox's Atlas. Now that dermatology is becoming better known, and day by day is being based on more secure ground, the manifestation of peculiar sequelæ in certain cases will assume due importance and attract greater interest. These cases may serve to direct attention to a new and unexplored field.

### CASE OF INGUINAL AND FEMORAL HERNIA OCCURRING ON THE SAME SIDE OF THE BODY.

By J. M. COTTERILL, M.B. EDIN., F.R.C.S.E.

THE subject of hernia is one full of interest to the surgeon; and this is mainly due to the fact that not only does considerable difficulty occasionally present itself in making an exact diagnosis, but that we so frequently meet with complications of widely different natures, such as inflammation, adhesions, strangulation, hydrocele, malposition of the testicle, and the like, giving rise in their turn to various symptoms and risks to the patient, and calling for a careful consideration and treatment of each case on its particular merits. In illustration of this statement the following case may be of some interest.

On June 15th, 1882, I was asked to see Mrs. G—, aged sixty-four, who was reported to be suffering from severe pain in the abdomen, persistent vomiting, constipation, and other symptoms of intestinal obstruction. The history of the case was, that eight days previously to my seeing the patient vomiting and constipation had set in, and, in spite of the adoption of the usual lay treatment in such emergencies, she had grown steadily worse, the abdomen becoming somewhat tense and very painful, and the vomiting after the fifth day of the illness becoming slightly fecal in odour and appearance. Getting alarmed at her condition, she sent for medical advice, and the gentleman who saw her, recognising her symptoms as those likely to be due to strangulated hernia, and, on examination, finding an inguinal hernia in her right groin, reduced it without difficulty, and left his patient, as he hoped, in a fair way to recovery. The following day, however, she was considerably worse, and symptoms of collapse so rapidly set in that at

noon she was fast sinking, and by the time I reached her house at two o'clock she had died.

I had an opportunity of carefully examining the body after death, and found that the hernia, which had been reduced over-night, and which was of the direct inguinal variety, had again protruded, owing no doubt to the constant vomiting; but it was easily capable of reduction, and it turned out on inquiry that the patient had suffered from this reducible hernia for some forty years past. At first I naturally suspected that this hernia had become strangulated, and had been reduced *en bloc*; but on making a more careful examination I discovered a small femoral hernia on the same side of the body, which had escaped previous notice from its comparatively small size and from the great development of superficial fat over the patient's body. This femoral hernia was about the size of a walnut, tense and irreducible, and there seemed every indication that it had been the cause of death. It seems strange that it had not attracted the notice of the patient, but she had made no complaint of it, and seemed to have been unaware of its presence, referring the pain and other symptoms to the inguinal hernia lying close above it. As no medical advice was sought until two days before death, when, judging from the symptoms, gangrene of the gut and peritonitis had supervened, it is not probable, even if the exact nature of the case had been then recognised and herniotomy performed, that the case would have terminated satisfactorily.

The comparatively rare occurrence of two forms of hernia on one side of the body, and the fact that one of these, apparently the fatal one in this instance, had been overlooked, seem to render this case deserving of record.

Edinburgh.

### THE INTRA-VEINUS INJECTION OF FLUID FOR SEVERE HÆMORRHAGE.

By C. EGERTON JENNINGS, L.R.C.P. LOND.,

RESIDENT ACCOUCHEUR, AND FORMERLY HOUSE-PHYSICIAN AT THE LONDON HOSPITAL.

ON August 20th, at about 3 P.M., M. A. S—, a patient of the London Hospital Maternity Charity, pregnant, and nearly at term, fell in the courtyard adjoining her house, suddenly becoming the subject of profuse ante-partum hæmorrhage. At 5 P.M. I found her collapsed to a marked extent, lying on a sofa in her bedroom, the pulse barely perceptible, the skin cold and clammy, extreme pallor of the face, an anxious expression of countenance, sighing respiration, and slight jactitation. Blood was flowing from the vagina; the mucous membranes were blanched. Upon examination, I found the os uteri fairly dilated, the right shoulder presenting; the membranes were unruptured, and the edge of the placenta could be felt just within the os uteri posteriorly.

At this critical juncture I remembered the cardinal rules laid down very clearly by Dr. Palfrey in his lectures on Obstetric Medicine for the management of cases of this description—viz., to arrest hæmorrhage, to correct the malpresentation with the least possible shock, and, by cautiously employing stimulants and restoratives freely, to allow the patient to rally and deliver herself spontaneously. A drachm of brandy with one of water was injected into the gluteal muscles; the membranes were ruptured, and the left leg brought down into the vagina with considerable ease, owing to the flaccid condition of the parts and the amount of general anæsthesia present. The abdomen was kneaded, the hæmorrhage ceasing. To have accelerated delivery at this period would, I think, have proved fatal. Two grains of sclerotic acid, in solution, were injected into the buttock, and the woman was covered up with blankets. I left an assistant steadily kneading the uterus, and returned to the hospital for a transfusion apparatus. Not being able to procure a blood-giver, it was determined to try a saline alcoholic intra-venous injection.

I may observe parenthetically that great difficulty was experienced in finding a vein, owing to the profound anæmia existing. The patient's right elbow was immersed in hot water, and the cubital triangle thoroughly sponged. These means, added to friction of the part and the adaptation of a

turn of a bandage around the arm, were successful in causing the veins to stand out with some prominence; an incision was made over the median basilic, the vein exposed, isolated, and an aneurism-needle armed with a double ligature passed beneath it. The distal ligature was tied, the vein opened, the nozzle of a three-ounce metal syringe, charged with the fluid already prepared, inserted; the proximal ligature tied loosely over the nozzle of the syringe, and the piston pressed slowly home. This was about 6 P.M., the woman being moribund. The syringe was emptied; it was disconnected, refilled and readjusted, the process being continued till sixteen ounces of fluid had been injected. Signs of animation very rapidly appeared—recognition of people present, speech, vision and hearing returned, and complaints of pain in the abdominal region were made. The syringe was withdrawn, the proximal ligature on the vein now tied tightly, the wound closed with the interrupted suture, and a compress and bandage applied. Another grain of sclerotic acid was injected hypodermically and the case left to nature, delivery occurring at about 7.30 P.M., without any further operative interference whatever.

I may add that the saline alcohol solution, employed in this case, consisted of twenty ounces of water at about 100° F., into which was stirred a powder containing exactly the following ingredients:—Chloride of sodium, fifty grains; chloride of potassium, three grains; sulphate of soda, and carbonate of soda, of each 2.5 grains; phosphate of soda ( $\text{Na}_2\text{PO}_4$ ), two grains. To the fluid thus prepared two drachms of absolute alcohol were added. The subsequent progress of the patient has been most favourable. The highest temperature (Aug. 23rd) noted since delivery was 102.4° F.; the wound at the elbow healed kindly, and the woman has proceeded to an uninterrupted convalescence.

I believe I am correct in asserting that transfusion is commonly regarded as a theoretical rather than a practical operation—as one to be performed in the theatre of a hospital, but not in the country village or wayside house. With the view of facilitating the method of intra-venous injection, Messrs. Maw, Son, and Thompson, have made for me a small case containing a few feet of elastic tubing, to be used after the principle of a nasal douche or syphon, cannulae of different sizes, a pair of dissecting forceps, with fine points, a scalpel, an aneurism-needle and ligatures, a graduated bottle for alcohol, and room for some saline powders. Here, within very small compass, the accoucheur has the means, with the addition of a jug of hot water, of combating very speedily the effects of alarming hæmorrhage. This is, I submit, a more practical method than the transfusion of blood; here no blood-donor is required, and no risk—it may be urged a trilling risk—to a healthy life incurred.

## EXCISION OF THE LATERAL HALF OF THE TONGUE BY WHITEHEAD'S METHOD.

BY BENNETT MAY, B.S., &c.,  
SURGEON TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

AT the present time, when the subject of excision of the tongue in cancer is somewhat prominent, I feel called upon to make a short record of the following case, which terminated fatally.

J. T.—, aged forty-four years, became an inmate of the Queen's Hospital on January 21st, 1882. He was suffering from an epithelioma of the right margin of the tongue, appearing as a foul ulcer about an inch and a half in length, and parallel to the long axis of the organ. It extended back to within a quarter of an inch of the palato-glossal fold, but was not infiltrated beyond its immediate base. The history pointed markedly to a local causation—viz., the ragged edges of a row of stumps, which after many months' irritation were extracted too late to arrest the progress of the disease. Under the angle of the jaw was a single glandular swelling the size of a pigeon's egg, slightly tender, but movable and circumscribed; it had come up suddenly within three weeks of his admission, and was thought to be subsiding at that time. He was otherwise in fair health.

*Operation.*—The patient, placed in a dentist's chair, was brought under ether, and the frænum divided with curved

scissors to give more room in the mouth. The tongue was then transixed with the bistoury, and split into lateral halves by cutting forwards. The scissors were used to sever the mucous membrane along the floor of the mouth, the palato-glossal fold, and finally the right half of the organ was severed on the level of the lower border of the maxilla. Bleeding was free, and required prompt attention for its arrest. It followed every cut, but it was not till the final severance that it welled in profusion from the main artery in the floor of the mouth. I did not interrupt the proceeding long to attempt to arrest it in detail, with the exception of securing a vessel in either half which had been severed during the splitting. The vessels were exposed by traction on the sound half of the tongue, and were secured by gutligatures without much difficulty. The gland was then removed through an incision over it, beneath the angle of the jaw, whilst it was made prominent in the neck by a finger in the mouth. Being a salivary gland, it easily shelled out until it held only by a small tag of tissue, which rather unfortunately was touched with the scalpel instead of being torn off, for a small vessel was severed, and continued to bleed into the mouth, the floor of which had been penetrated. This bleeding was more difficult to arrest than that from the tongue, and the wound had to be thoroughly everted before the little point could be found. The resulting wound, however, which extended from the back of the floor of the mouth to beneath the angle of the jaw, afforded an excellent line of drainage, and a tube was retained there for the purpose. Every precaution was taken in the after-treatment, as described in THE LANCET of June 10th. On the third day I thought he was out of danger, for he had rallied well from the operation, was free from fetor of the breath, and with excellent drainage through a tube below the jaw. On the fourth day the pulse and temperature went up, and he began to cough purulent mucus from the trachea. There did not seem enough mischief in the chest, however, to account for his serious illness. On the same day, after thoroughly irrigating the mouth, I let him have a little milk to drink, and soon afterwards he was seized with pain in the abdomen, followed by diarrhoea and hæmorrhage from the bowels. These continued unchecked till the eighth day, when his death took place rather suddenly after intestinal bleeding. No post-mortem was permitted, but the cause of death is believed to have been gastro-enteritis and purulent bronchitis.

The principal point of interest in the case is that of hæmorrhage from the mode of operation, and its bearing on the fatal result. Although free, the bleeding was controllable, and was arrested by promptly securing three or four vessels. I cannot say that none entered the air-passages, though the operation was not embarrassed by this cause. It was not formidable or dangerous *per se*, further than it may have opened the way, as it does so fearfully in these cases, to other complications, such as admission of blood to the lungs and the ready onset of septic infection. Having only to remove one-half of the organ, I was at great ease and advantage in securing the vessels by traction on the sound portion, but if the other half had required removal I should not expect to have fared so well. I felt this at the time. There would not have been the same facility in exposing the bleeding vessels. For the same reason, after the first splitting of the organ, I made very little delay to arrest bleeding in detail. I found more loss than gain by this, the severance of one-half being effected very quickly, and there being no profuse bleeding till the final cuts. I have seen nearly as much bleeding follow the use of the écraseur, and without the great advantage of being securely arrested before the patient left the operating-table, as was the case with this patient. I do not wish in any way to associate the fatal issue with the special method of operating. I hardly know why death should have occurred, or how far the hæmorrhage of the operation may have contributed to the fatal result; certainly the gland was as much to blame as the tongue. Nor do I wish to disparage the operation on such limited experience. But it appears to me that Mr. Whitehead underrates the amount of bleeding which may at times be encountered. The operation is easy of performance and rapid in execution, and in his hands has yielded excellent results, whilst his rules for after-treatment are most valuable. In the meanwhile the possibility of having to encounter such a case as that of Mr. Treves (THE LANCET, April 22nd), although doubtless exceptional, and my experience in this, one, will deter me from resorting to a cutting operation with-

out adopting Billroth's preliminary step of securing the lingual arteries. Any operation, to be satisfactory, should provide against the admission of blood into the air-passages, and should also secure subsequent drainage below the jaw, and my own experience leads me to believe that these desiderata can be most surely attained by an operation which includes division of the lower jaw whenever the entire organ is to be removed.

## EXCISION OF THE ENTIRE TONGUE BY WHITEHEAD'S METHOD.

By ANDREW MARSHALL, M.D.

A FEW months ago a brief report was published in the columns of THE LANCET of a case of excision of the entire tongue performed by me according to Mr. Walter Whitehead's method, in which there was an entire absence of the difficulties and dangers which some surgeons have experienced in the course of this operation. The process was found to be easy and expeditious, the amount of blood lost quite insignificant, and the result satisfactory. Another similar case has lately occurred in my practice which has tended to confirm in my mind the favourable opinion of the operation which I formerly expressed.

W. D—, aged forty-eight, by occupation a wheel-smith, living in Preston, and suffering from cancer of the tongue, was first seen by me on July 22nd, in consultation with Dr. Lightbourne. The disease at that time involved nearly the whole tongue, excepting the anterior third. It was worst on the left side, where there were much enlargement, induration, and ulceration. There also the tongue was partly bound down by infiltration of the subjacent tissues; and attempted movements by the patient, or manipulation by others, produced extreme pain.

The man was evidently a great sufferer, exhibiting in a marked degree the usual symptoms of his distressing complaint—viz., constant pain, aggravated by talking, masticating and swallowing, great fetor of the breath, and profuse salivation. The disease had been in existence for several months. It was first noticed as an indurated spot on the left side. No cause could be ascribed for the existence of the malady. There were no sharp teeth to account for it. The patient had been a temperate man, was not a smoker, and said he never had syphilis. There was no history of cancer in the family so far as could be ascertained. We advised removal of the whole tongue, considering it expedient as a palliative measure, although of course not likely to result in anything better. It should be stated that Dr. Lightbourne had previously given him the same advice, which, however, he then declined. After a few days' consideration he gave his consent, and the operation was performed on July 28th. Mr. Whitehead's directions were strictly followed, and surely that is necessary if a fair estimate is to be formed of his operation. After the first few snips with the scissors, blood began to flow rather freely, but the prompt application of small sponges not only prevented any reflux of the blood into the air-passages, but also speedily arrested the flow sufficiently to allow the operation to be safely proceeded with. Bleeding took place from the right lingual only, and pressure with the finger sufficed to stop it; the left lingual was never seen. The later stages of the operation were accompanied by very little hæmorrhage, and after its completion there was hardly any at all. Altogether there was not much, probably from two to four ounces, and there was no difficulty whatever in controlling it.

There was nothing specially noteworthy in the after-treatment. No food was given by the mouth for three days. Antiseptic washes and inhalations were used. Great relief from pain followed the operation and a good recovery was made, but of course the benefit is only temporary, a cure under the circumstances being impossible.

A difference of opinion still exists amongst surgeons as to the relative merits of Mr. Whitehead's operation, but this difference refers principally, or perhaps solely, to the danger from hæmorrhage, it being very generally admitted that "if the question of probable bleeding be put aside the operation would be in every way excellent. By its means the tongue can be removed entire, with ease, precision, and rapidity; the neighbouring parts are but little disturbed, and all the

evils incident to the crushing or bruising of tissues (as involved in the use of écraseurs) are avoided." With regard to hæmorrhage, Mr. Whitehead asserts that it "is easily controllable and usually trifling." Some operators have not found it to be so, however, for cases have been recorded in which the hæmorrhage was "very profuse" and even "terrific." It does seem desirable therefore to obtain an "accumulation of cases from different sources" in order to determine the real extent of this danger, and to discover, if possible, the true explanation of the "conflicting statements" which have been put forward with regard to this subject. Preston.

## ON TWO CASES OF HEPATIC ABSCESS; RECOVERY.

By F. C. BARKER, M.D., F.R.C.S.I.,  
BOMBAY MEDICAL SERVICE.

CASE 1.—D. S—, aged about twenty-five years. Admitted to Surat Civil Hospital August 13th, 1877. Liver enlarged to about a handbreadth below costal margins, and upwards to an inch below nipple. Tenderness and loss of appetite. Attack began ten days ago. No pain in shoulder. Temperature normal. Given twenty-five grains of ipecacuanha. No emesis followed.—Aug. 14th: Severe hepatic pain. Slight fever in the night with "cold" (rigor?) reported. Tongue slightly furred. Given a calomel and jalap purge.—19th: A distinct fluctuation in right hypochondrium, with fulness here and in the chest above, and obliteration of the intercostal depressions with great tenderness. Tapped in hypochondrium with aspirator and No. 2 needle; twelve ounces of reddish-brown fluid, abounding in hepatic cells, drawn off from a cavity evidently large, judging from the free movements of the needle without encountering the opposite walls. Allowed two ounces of country spirit daily as he was reported an habitual drinker. Ordered thirty grains of chloride of ammonium three times a day.—22nd: Partial relief to symptoms since tapping, but swelling returning. Temperature 100°. Chloroform given and an incision made close to puncture of 19th, about an inch and a half long, passing through the rectus, which was torn through with a director, down to its posterior sheath. Dry lint into wound and poultice.—23rd: Abdomen ascitic and feet slightly cedematous.—26th: As no bursting had taken place into the wound a finger was introduced, and the remaining covering of the abscess divided with a scalpel, on which about forty ounces, chiefly pus, flowed, a small quantity of bile-tinged fluid following. Drainage-tube introduced, and carbolized oiled lint pad applied. Abdomen and lower part of chest firmly bandaged. Ordered egg mixture.—27th: Abdomen reduced in size. No fluctuation. Discharge about two ounces. Pulse 76; temperature normal.—28th: Pulse 97. Abscess admitted a probe five inches backwards. Discharge less. Pressure steadily kept up on abdomen during dressing. Skin generally becoming dirtier and looser.—29th: A great falling in of abdomen has occurred from pressure of the bandages. Discharge in great measure bilious.—30th: Pulse 100. Discharge still bilious.—31st: Same. Abdominal bandages slackened. Castor oil.

Sept. 2nd: Stools free and well tinged with bile, contrasting strongly with their previous clayey colour; bile apparently diverted from abscess to bowel. Its reappearance in the motions and disappearance from the abscess allayed fears of injury to the gall-bladder or ducts. Lateral space in abscess lessening; bandage a little tighter.—3rd: Pulse 97. Discharge nearly free from bile, purulent, rather thin.—4th: Pulse 91. Thermometer in abscess showed 99° 8'.—7th: Daily discharge now about three or four ounces.—9th: Discharged a piece of thin membrane about two inches square, tinged with bile.—23rd: Rupial eruption on back of hand.

Oct. 4th to 10th: Discharge much less. A small sore on glans penis and a general ulcerative eruption covering the body by the 10th, with increase of discharge from abscess to about an ounce.—19th: A great decrease in discharge since the 13th, on which iodide of potassium was increased. Crusts of eruption separating.—28th: Drainage-tube discontinued. Improvement uninterrupted from this date.

Nov. 10th: Abscess scabbed over; health good; become fat. Discharged.

The total amount of discharge during treatment was calculated at over four pints and a half, including that atappings.

*Treatment* (essentially) after incision of abscess:—Stimulants; alimentation; cod-liver oil; iron; quinine; nitro-muriatic acid; frictions of cod-liver oil and iodide of potassium on appearance of syphilitic eruption, which, under its use, disappeared as promptly as it had supervened severely, and in evident connexion with the persisting suppurative tendency in the liver.

CASE 2.—Mr. G—, aged thirty-nine, tall, sanguine temperament and spare active frame, and remarkable powers of recovery from repeated illnesses, having had several attacks of liver congestion, or inflammation more or less acute, and once evidently connected with malarious fever, and on subsidence of which the liver got well. On July 23rd, 1879, two days after hard racquets, followed by iced drinks and while out of practice, he was seized with lancinating pain in right and left hypochondria, which became more intense next day. Purgatives for costiveness having partially acted, opium gave temporary relief, but the temperature rose and remained so, with evening remissions till the 31st, when a sudden fall of three and a half degrees, with a profuse perspiration, accompanied the discovery of a deep-seated tender induration in the epigastrium, two and a half inches in diameter. No fluctuation. This was found, however, on August 5th, and on the 8th became so superficial that puncture was practised with a large trocar and cannula after a short cutaneous incision, and a grooved needle exploration gave exit to a drop of pus. About an ounce of healthy pus mixed with blood afterwards escaped. On this ceasing a carbolic oiled strip of lint was inserted through the cannula, and poultices kept on. Subsequent daily discharge very slight, and relief marked, temperature remaining at 98.4° and 99°, till the 17th, and a previous severe hæmorrhagic and dysenteric purging at once and finally ceasing. The discharge, however, continued of a disappointing character, scanty and reddish; pulse, though only from 62 to 77, laboured and unrhymical; temperature showing the slight evening rise to 99°; slight headache and disturbed sleep, with bad dreams. On the 18th a return of enlargement round site of abscess; temperature rose to 101.6°. Leeches, fourteen over liver and four to anus; milk diet.—19th: Slight fall of temperature; leeches, six and four.—20th: Further fall to 99.4°; leeches, eight and two.—21st: Further fall to 99.6°; leeches, twelve over liver.—22nd: Further fall to 98.4°, and evening 99°. From this date convalescence progressed, and he departed, by sea, for Bombay, where, under appropriate treatment, comprising blisters, iodine painting, chloride of ammonium, nitro-muriatic acid, nux vomica, Carlsbad salts, and no stimulants for a time, the small remaining sinus healed, and his general health was restored. On inspecting him again, at Ruttonagiri on November 15th, I found him doing well and engaged in hard official work, with which he was occupied till his departure for Europe in May last.

*Remarks.*—In THE LANCET, Dec. 21st, 1878, p. 871, Surgeon Major Furnell, speaking of the aspirator, says: "The abscess is tapped again and again with relief." This is precisely what promised to occur in my Case 1, and appears, as Dr. Furnell says, an inevitable consequence of the use of the aspirator in all large abscesses. The liver must have something to fill the vacuum, and the readiest things are pus, blood, or liver tissue. A week after the aspirator drew twelve ounces the scalpel incision gave vent to forty ounces. No further operation was required. But in this case, I think, immense benefit was derived, and for obvious mechanical reasons, from the firm abdominal bandaging. Here was an equable pressure aiding contraction from without, and in no way conducing to internal breach of surface, like the suction force of an aspirator.

Since reading Dr. Furnell's cases and remarks, I should certainly prefer (to even the small piece of drainage-tube I used) the oiled lint strip, as less interfering with nature while sufficiently keeping open a way of exit for discharge. It answered well in Case 2, introduced through the cannula as he advised.

In Case 1, a severe syphilitic taint, declared by the rupia, warranted every possible blood-restoring and supporting measure whose good effects, coupled with the iodide, were shown by the progress of the case; whereas in Case 2 a directly opposite line of treatment was as clearly indicated

by the sanguine temperament and purely phlegmonous character of the abscess, and that which answered best was found to consist of leeches, low diet, no stimulants, and repeated doses of castor oil.

Dr. Furnell's directions for the preliminary incision should be paid special attention to. The grasp of the skin and underlying tissues on a large trocar with an incision insufficient in length and depth, is such as to necessitate a degree of force in its introduction which might be dangerous in a thin-walled abscess, and in any case gives a needless shock.

Warrenpoint, County Down.

#### NOTE ON THE

### TREATMENT OF CONTRACTED FINGERS.

By EDWARD BELLAMY, F.R.C.S.,  
FELLOW OF KING'S COLLEGE, LONDON.

A POWERFUL man some months ago scratched his little finger with a meat-bone. The usual train of symptoms followed, and when I saw him the tip of the little finger was so tightly approximated to the palm that no force could separate it, and strong fibrous bands corresponding with the primary flexures were readily observed, and as I thought the tendon was uninvolved, and still ran in a tolerably free theca, I divided the bands with a von Graefe's iridectomy knife, which is singularly useful for fine plastic work, and extended the fingers forcibly. No good came of this proceeding. I subsequently placed him under an anæsthetic, and carefully and thoroughly extirpated the entire cicatricial tissues, and divided the tendon, with antiseptic precautions. The finger was carefully retained in the straight position, a metal circlet was made for the wrist, and a piece of stout steel clock-spring welded on to it. This steel spring was carried up the dorsum of the finger and suitably attached to it. By its tension it effectually kept the parts on the stretch, and when the wound had healed, passive and active movements, conducted by the patient himself, brought about an excellent result. The finger is as straight as the others, and will be, no doubt, ultimately quite as useful.

Wimpole-street.

OF

### HOSPITAL PRACTICE, BRITISH AND FOREIGN.

*Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.*—MORCAEVI De Sed. et Caus. Morb., lib. IV. Proœmium.

#### CHARING-CROSS HOSPITAL.

CASE OF TUMOUR OF BLADDER; DIGITAL EXPLORATION  
THROUGH MEDIAN INCISION; REMOVAL OF  
GROWTH.

(Under the care of Mr. JOHN H. MORGAN.)

FOR the following notes we are indebted to Mr. W. H. Colman.

Edward J—, a labourer from Great Wakering, Essex, aged sixty-five, was admitted to the hospital at the beginning of the year, under the care of Mr. Bellamy. He stated that about fifteen years ago he had felt pains after micturating. The pain was at first of a cutting nature, and was referred to the region of the neck of the bladder, but there was not at the time any alteration in the character of the stream from the urethra. In the course of time he found that the frequency of micturating gradually increased, and occasionally the urine was mixed with large quantities of blood. Previous to this time he had been healthy, his habits were temperate, and his family history was exceptionally good. During the last few years he had occasionally passed gravel, sometimes pieces coming away with the urine as large as wheat-grains.

On admission he was found to be a well-built muscular man,

of rather florid complexion, and with hair turning grey. Notwithstanding the frequent loss of blood, he declared that he had not grown perceptibly thinner. During the day, he required to pass urine frequently, but the length of the intervals was very variable; at some times he was able to go two hours, at others being compelled to micturate every five or ten minutes. Movements increased the frequency, and gave rise to some pain, which, however, was never excessive. There was never any retraction of the testes, nor had he ever suffered from sickness or diarrhoea. He was sounded by Mr. Bellamy, but no calculus could be detected, and he was ordered a mixture containing small quantities of tincture of perchloride of iron and tincture of opium. The urine was almost always tinged with blood, but the amount and colour varied greatly; at times the urine being bright scarlet, and at others the amount of blood being so small as only to be detected by microscopic examination. No calculous matter was passed during his stay in the hospital, but when the quantity of blood in the urine was larger there was usually to be found a large number of whitish flocculent masses at the bottom of the receptacle, which proved, on examination, to be small amounts of decolorised fibrin.

During the absence of Mr. Bellamy the patient came under the care of Mr. Morgan, who on sounding the bladder was unable to detect the presence of any calculus, but the sensation was given of the presence of a soft uneven mass lying at the posterior part of the bladder. Examination per rectum showed the prostate to be slightly enlarged, but did not assist in determining the nature or size of the new growth. Accordingly the patient was placed under the influence of ether and again sounded, when the previous conjecture was still further strengthened. The bladder was then washed out by means of an apparatus which Mr. Morgan has lately devised for the examination of detritus after lithotomy. The result of this was the removal of a large quantity of the decolorised fibrin with a good deal of fresh blood; but under the microscope no characteristic epithelial cells could be detected.

On May 11th the patient was again placed under ether, and a staff having been passed, and the patient being in the position for lithotomy, Mr. Morgan, having first divided the skin in the middle line a little above the anus, passed a lithotomy knife down to the groove in the staff and made an incision of the urethra of about three-quarters of an inch in length. Through this wound the left forefinger, aided by the pressure of the right hand on the abdomen above the pubis, was able to explore the greater part of the walls of the bladder, as pointed out by Sir Henry Thompson. There was found to be a quantity of soft velvety growth springing from the posterior wall, and generally diffused, but one large mass grew as from a pedicle, and this was easily grasped between the blades of a lithotrite, and removed through the incision. A full-sized catheter was introduced through the wound and secured. Very little bleeding followed the operation, and the patient passed a comfortable night. On the following day the catheter came out of its own accord, and was not replaced. On the second day the patient was slightly feverish, but after the bowels had been well relieved this passed off, and he made a rapid recovery; so that he was up and about the ward on the sixth day after the operation, urine being passed by the urethra only every two or three hours, and containing hardly any trace of blood.

The growth removed resembled a filbert in size and shape, and in structure consisted of a rather contracted pedicle from which sprang innumerable branchlets, which again were subdivided into small villous prolongations. The villi consisted of a basement containing vessels, and were covered by layers of epithelium of a squamous character.

At his own request, the patient returned home at the end of a fortnight, and Dr. Raper, who has attended him since, reports in a letter dated July 12th, that he "remained very much better for some time after he returned home; his water was comparatively free from blood, and he only required to pass it once in two or three hours; sometimes there was a little blood-stained mucus at the bottom of the chamber, and a few gritty particles passed at times, similar to what he had been passing before he went to the hospital, but less in quantity and in size. Since Friday last he has not been so well, the blood has much increased and he has to pass water more frequently, often two or three times in an hour; also the water passes less freely, and he has more pain and feels weaker."

## DISTRICT HOSPITAL, WEST BROMWICH.

### RUPTURE OF LIVER; DEATH IN THIRTY-FOUR HOURS.

(Under the care of Mr. SANSOME.)

G. R—, aged forty-six, was admitted, Aug. 25th, about 4 P.M. He was a labourer, employed at some chemical works near the hospital. In the afternoon he was standing behind a stationary truck for the purpose of coupling it to others coming up behind and drawn by horse power. For some purpose he stepped out before the hinder trucks had been quite drawn up, the buffer struck him in the back, knocking him forward on to the buffer of the stationary truck with such force that the latter was propelled about two yards.

On admission he was suffering from severe shock, his features being pinched and sallow, surface cold, and pulse feeble. The conjunctivæ were not discoloured, and there were no marks of violence about the body. The area of hepatic dulness was somewhat extended posteriorly. Hot fomentations were applied, opium administered internally, and milk only ordered. About midnight eight ounces of clear, high-coloured urine were drawn off, but catheterism was subsequently needed. Next morning the same conditions obtained, except that the dulness was not so extensive. He suffered acute pain and nausea; the shock seemed intensified, and stimulants were ordered, but without avail. About 8 P.M. all pain ceased, and he expressed himself much better. This continued till 11 P.M., when delirium supervened; he rapidly sank, and died at 12.30 A.M. on the 26th.

At the post-mortem, fourteen hours afterwards, the body was found to be well nourished and muscular. On opening the abdomen a large quantity of clear bloody fluid escaped, and on the posterior border of the right lobe of the liver was a gaping jagged wound, three inches in length and one-inch in depth at the centre, which was the deepest part. Three inches anterior to this was another wound two inches long, about one-twelfth of an inch deep, but in which the capsule was not in its entire extent torn through. The gall-bladder and duct were uninjured. There were numerous clots around, and the ascending colon and surrounding structures were much discoloured. The other organs were healthy.

It will be observed that the patient lived thirty-four hours after the receipt of the injury.

## GUEST HOSPITAL, DUDLEY.

### LATERAL LITHOTOMY; EXTRACTION OF A LARGE URIC ACID STONE, WEIGHING THREE OUNCES AVOIRDUPOIS.

(Under the care of Dr. UNDERHILL.)

B. J—, aged twenty-three years, a fender maker, of average development, but very anæmic, was admitted on June 2nd, 1882. There was no particular family history, and he had had no illness of moment until the present. He stated that when a schoolboy he experienced pain when micturating; that this had continued until the present time; that slime sometimes followed the urine, and that the stream had sometimes stopped suddenly, but that he had not observed any blood in it. For five months before admission he did not work, and remained chiefly in bed, the agony during micturition, which was frequent, being intense, and the urine turbid. During that time a sound was twice passed without a stone being detected; possibly it did not completely enter the bladder, as there was slight hypospadias, with much spasm and irritability of the urethra. Under ether a large stone was detected on June 9th. The man being under the influence of ether, left lateral lithotomy was performed in the usual way; the stone was grasped with difficulty, and the forceps slipped twice during the attempt to remove it (as there were none at hand suitable for a very large calculus). The incision was then extended in a backward direction with a bistoury; the stone was again grasped, and after long and steady traction, with much force, was extracted. The sphincter ani was slightly lacerated during the last part of the operation. A fair amount of hæmorrhage took place, which soon ceased on bringing the thighs together. The mucous membrane of

the bladder was felt to be roughened. The shock of the operation was severe, and opium was administered on recovery from the ether. The stone was irregularly oval; apparently it consisted of uric acid, with a thin phosphatic coating. It weighed just over eight ounces avoirdupois; length,  $3\frac{1}{2}$  inches; breadth (greatest),  $2\frac{1}{4}$  inches; circumference at greatest breadth,  $7\frac{1}{4}$  inches.

June 22nd.—There have been no unfavourable symptoms. Temperature has only reached  $100^{\circ}$  F. on two occasions. Urine was passed to-day, for the first time since the operation, per vias naturales.

July 22nd.—Full diet has been taken since June 28th, and the man has become quite fat. A fistula remains at the anterior part of the incision, but very little urine passes by it, and that only occasionally. Some small phosphatic scales have been expelled per urethram. He walks about a little. A mixture of half a drachm of dilute nitric acid with cinchona was ordered, and the sinus to be injected with nitric acid lotion four times a week.

August 5th.—Patient remains in the hospital; the fistula has not yet closed. General health good.

### BLACKBURN AND EAST LANCASHIRE INFIRMARY.

COMPOUND DISLOCATION OF ASTRAGALUS FORWARDS AND INWARDS; EXCISION.

(Under the care of Dr. STEPHENSON.)

IN THE LANCET of September 2nd, a case is reported from St. Albans of a simple dislocation of the astragalus. As complementary to it the following may not be without interest.

On July 3rd, J. K.—, while working in a gravel pit, was buried under a large quantity of falling earth and stones. On admission into the infirmary, he was found to have a gaping wound, some four inches long, extending over the inner and dorsal surfaces of the left foot. Through this the head of the astragalus protruded. The foot itself was twisted outward. There was much swelling and effusion into the soft parts. The tibia and fibula were intact, and the ankle-joint uninjured.

Ether being administered, reduction was attempted. This failing, and the bone seeming much detached, it was decided to excise the whole of it. This was readily done. Drainage being provided, the foot was carefully adjusted to a back-splint with foot-piece. The wound healed rapidly; the drain was removed on the fifth day, and the parts quite recovered by July 30th.

Owing to the extensive contusion the outer side of the leg received from the falling earth, large sloughs formed up the leg, denuding in one place the fibula for more than an inch. This delayed the man's discharge from hospital until September 1st. He can walk with ease, the new false joint admitting of both flexion and extension. The amount of shortening of the limb is barely appreciable.

### KASHMIR HOSPITAL.

TWO CASES OF HYDATID OF THE LIVER.

(Under the care of Mr. DOWNES.)

CASE 1.—A middle-aged woman was seen in September, 1877. There was a large tumour extending from the liver to about two inches below the umbilicus; it was most prominent a little above the level of the umbilicus on the right side, and in one spot where it particularly bulged distinct fluctuation showed that it contained fluid. The history of the case and the appearance of the patient seemed to indicate that it was not an abscess; there was considerable pain, but no fever, and the pain had come on gradually and seemed to be due to pressure only. Hydatid of the liver was diagnosed; and the tumour was tapped with a very small trocar and cannula. The fluid withdrawn from it (which amounted to about half a gallon) was quite clear and non-albuminous. The tumour disappeared, and the woman experienced great relief. The patient remained quite quiet for some days. After about a week fever supervened, and there was tenderness at the spot which had been punctured. The fever disappeared, but a swelling was observed near the spot of puncture, and the tumour evidently contained fluid; this swelling increased for a few days, when it became

stationary. The tumour did not extend below the level of the umbilicus. She remained in hospital for two or three weeks, when she returned to her home. She and her husband were very desirous that the tumour should be tapped again, but this was not done, as it was thought that it might become absorbed.

When the woman left the hospital the swelling had not materially decreased, but there was no tenderness, and the tumour extended only to about the level of the umbilicus, instead of occupying a large part of the right iliac fossa, as it did before the operation. The patient has not been heard of since.

CASE 2.—The subject of this case was a middle-aged man, who was seen in September, 1879. There was a round tumour in the epigastric region extending down to the umbilicus, and apparently connected with the liver. It was particularly prominent in the very centre of the epigastric region, and there was indistinct fluctuation. The tumour was very tense, and pressure gave rise to very great discomfort, but not amounting to acute pain. The tumour did not extend much to either side, and this made the diagnosis a little puzzling; but, taking everything into consideration, it seemed certain that it was a case of hydatid of the left lobe of the liver. The patient lived a long way from the hospital and he could not go there. Mr. Downes then and there in the open fields, surrounded by an interested group of villagers, inserted a small trocar and cannula, and drew off more than a quart of fluid, which was slightly turbid. This gave marvellous relief immediately. The man was carried to his cottage and kept quiet for some weeks.

After about a month or six weeks he paid a visit to the hospital. He was not then suffering from any pain or inconvenience, but a small tumour, apparently containing fluid, was in the position of the original tumour. As in the former case, this reaccumulation of fluid was not tapped, and the patient was told that this swelling would probably subside of itself. He did not present himself again, so it is hoped that he considered himself cured.

These two cases illustrate what has already been written by the late Dr. Murchison—viz., that hydatid tumours of the liver may be tapped in the majority of instances with a small trocar and cannula without danger; and that this proceeding gives immediate and complete relief, and in many cases may cure the disease.

### Reviews and Notices of Books.

*Human Parasites.* A Manual of Reference to all the known Species of Entozoa and Ectozoa which (excluding the Microphytic, Confervoid, and Simple Sarcodic Organisms) are found infesting Man. By T. SPENCER COBOLD, M.D., F.R.S., F.L.S. London: Longmans, Green, and Co. 1882.

THE author of this work has done so much to advance our knowledge on the subject of which it treats that any further contributions he makes to it are always welcome. We have here in a concise and compact form a synopsis of all the species of animal parasites infesting the human body, including those whose "visits may be little more than instantaneous." Each species is described, its habitat and intermediate host stated, its larval condition noted, and mention made, when necessary, of experimental researches upon it. Lastly, reference is made to the literature of the subject, which in the case of the *Filaria Bancrofti* (syn. *Fil. sanguinis hominis*) comprises a complete bibliography, occupying more than five pages. The utility of the book is self-evident, and we hope that its publication may do something to remedy the state of affairs to which the author alludes in his "concluding remarks"; and to show our freedom from the "insane prejudice" therein referred to, we cannot do better than transcribe these militant words for the benefit of those concerned who may not have the opportunity of perusing them in the original:—

"The literature of the subject of microphytes has of late increased to such an extent that it would require several pages for the mere enumeration of published memoirs. As a model of the exhaustive treatment of one department,

ter's work on *Spirillum Fever* leaves d. If our leading hospital physicians possible for any one human intellect to knowledge of all that appertains to diseases, and their treatment, they must they greatly deceive themselves. Not be informed that by restricting their place subjects, they do serious injustice on of medical practitioners. An insane al knowledge has recently sprung up. ceed from individuals who are ignorant ce, it can only have for its object the e investigation and the suppression of progress. In civilised communities the e of division of labour is intimately ublic welfare, and those who arrogate session of universal medical knowledge o the cause of suffering humanity. s, like other good things, are liable to sh developments of culture are based dent education at our medical schools re need be no fear as to the general y department of the science of medicine lgar and unqualified persons demands e secure the approbation of every right- e medical profession."

*of the London Hospital.* Compiled on of a Committee appointed by the Medical Council. London: J. and A.

poesia of the London Hospital having ut of print, the Medical Council con- ter might with advantage be revised, nittee of the medical staff to report on sult is the work before us, which is pharmacopoeia, but a guide to the art dition to the hospital formulæ, we have collection of diet-tables with directions eptonised food, and an appendix nstructions for taking cases in the wards, and urea, for preserving and staining e treatment of cases of poisoning, deal of very useful and practical infor- as been thoroughly done, and many of rely new. In the *materia medica* we e introduction of sanguinis bovinus inated desiccated bullock's blood—a used chiefly in the form of an enema in and other diseases in which food is not ch. The list of enemata is very com- sed nutrient enema is of especial value. id extract of ergot is an excellent pre- found of considerable use in obstetric malt and extract of malt and cod-liver been admitted as pharmacopoeial pre- poth of such inestimable value in the ing diseases that no hospital or public e treatment of the sick can afford to do ach has been deemed worthy of inser- sly enough, the more popular *Grindelia* cted. Directions are given for the pre- ferratum and gossypium iodatum, both value. The list of injections for hypo- l, and includes carbolic acid, sclerotic ergot, perchloride of mercury, morphia, quinine and strychnia. The only nce is apomorphia, a most valuable oning. Under the head of *Lincti* we e; a morphia linctus containing about quior with a little spirits of chloroform e would be a useful addition. The

aconite mixture—five minims in each dose—is far too strong, and the caution respecting its use in this quantity is not sufficiently emphatic. In the majority of cases the dose of the active drug in the mixtures errs, if at all, on the side of safety. It may be noticed as a matter of curiosity that there is a mixture of Chian turpentine. Under the head of Powders we find pulvis agarici, "powder of dried mushroom," of which the dose is given as from ten to twenty grains. The definition of the drug to be used is in this case not sufficiently precise. As far as we are told, it might be any mushroom. As a matter of fact, it is of course the agaric of the larch which is intended, a drug now largely employed in the treatment of the night sweating of phthisis. It should be remembered, however, that the agaricus muscarius has been recommended for the same purpose, and the substitution of one species for the other might be attended with disastrous results. A few drugs are omitted of which we should have been glad to see some mention; fortunately, however, only a few. A substitute for pancreatic emulsion might be introduced in the next edition, together with mixtures of pulsatilla, hydrastis, and nitro-glycerine.

*The Surgery of Deformities.* By E. NOBLE SMITH, F.R.C.S. Ed., L.R.C.P. Lond., Surgeon to the Farringdon Dispensary. With Illustrations. London: Smith, Elder, and Co. 1882.

THIS is a well-meant attempt "to produce a practical and useful guide to the diagnosis and treatment of Deformities of the Human Body." No claim to originality is made, and to a very large extent the teachings and writings of Adams, Little, Chance, Stafford, and Shaffer have been laid under contribution, and the author has managed to give a useful epitome of the views of these authorities. In many places we find it wanting in practical details, and in the matter of diagnosis in particular the reader will often look in vain for substantial help. We are sorry that the great advance in surgical treatment during the last decade does not appear to be appreciated by Mr. Noble Smith, who, in adversely criticising the operation of resection of the tarsal arch, says, "The most rudimentary knowledge of the etiology of the various forms of blood-poisoning ought to make even a bold surgeon hesitate before exposing a patient to the risks of absorption of the septic debris, which must of necessity remain in such a wound"—the italics are ours. We are tempted to reply, that "the most rudimentary knowledge of the etiology of sepsis ought to make even a bold writer hesitate before speaking of decomposition as a necessary event in a wound made by a surgeon!" Our surprise, which was extreme, when we found that the author of "The Descriptive Atlas of Anatomy" states that the medulla oblongata is continued in the spinal canal, has been even more excited by reading a few lines lower down, in the section devoted to "disease of the upper two cervical vertebrae," that "even when paraplegia occurs from pressure upon the cord the patient may recover from the severer symptoms." As pressure upon the other portions of the cord is elsewhere treated of, this sentence must of necessity refer to paraplegia from pressure upon the highest part of the spinal cord, which only a few lines above is called the "medulla oblongata." "The most rudimentary knowledge" of the instantly fatal effects of paraplegia from pressure upon this part of the cord would have saved Mr. Noble Smith from this error. In several places we noticed the names of authorities referred to misspelt: thus we find references to "Althus," "Diffenback," "Hay" of Leeds, and "Prescott Hewitt"!

#### OUR LIBRARY TABLE.

*The Annual Oration delivered before the Medical Society of London, May 1st, 1882.* By E. SYMES THOMPSON, M.D., F.R.C.P. London: Adlard. 1882.—The subject chosen for this oration was "The Old Founders and the New

Remany Fellows," in which the author traces the lives of such men as Fothergill, and many others less known to fame, as Vesuvius, Billings, Charcot, Volkmann, &c. The oration of the Congress being seized to e in the Society. The portraits of the "f" in a frontispiece reproducing the well-known possession of the Society. The oration is in a readable style, and the interest is throughout.

*The Physical Signs of Pulmonary Disease.* Ed. Edinburgh: MacLachlan: Simpkin and Marshall. 1882. A well-written book, intended for use in the study of medicine. The author has evidently studied the subject, and has incorporated in the book common views of Laennec, Skoda, and Walhe. It follows the instruction contained in the foundation for physical examination, and is characterised by an over-refined and practical working. Dr. Seell is a competent and deals with broad, well-known facts conveying to the reader as clear a picture as has been needlessly rendered by the use of terms in different senses.

*The Illustrated Quarterly Journal of Surgery.* Edited by G. H. Fox and F. R. Jones. New York: E. B. Treat, Broadway. A well-written and excellent character of the journal. The subjects are dealt with as follows: Intestinal ulcer, a new method of treatment; case of congenital keratoma, papilloma (two cases), therapeutic value of elastic tension in the treatment of the same. Dr. Chamberlain describes the value of irrigation for purposes of irrigation of heat and cold. He maintains that irrigation is far superior to the lead catheter, especially because they are not so liable to be dislodged, and can at any time and by a simple manipulation be removed for individual cases. Dr. McLachlan gives a successful cure of peritonitis. The numerous illustrations make the journal quite plain—a feat of extreme difficulty. Descriptions are given. One chief feature in these cases was making an incision in the perineum: the urine was voided several times a day, and thus the parts were kept at perfect rest until healing was complete. Wounds healed very quickly.

*La Lithotritie doit être faite sans Trauma.* Dr. F. LAURENT, Lauréat de l'Institut. Paris: 1882.—This is a reprint of a paper in the *Gazette des Hôpitaux*, in which he gives a very emphatic answer in the negative to the question whether it is a rigid disciple of Civiel's method to be a rigid disciple of Civiel's method of the urethra and bladder. The main thing to be observed in the operation is that it can be done without any lesion of the bladder by injecting or aspirating; but the risk he prefers to leave the fragments in the bladder; and he also cautions against the use of the aspirator. He refers to Bigelow's practice of preventing the bladder by an elastic ring encircled around the neck of the bladder. He says that the theory agrees with the practice, and that the operation of late years has been clearly shown of late years that the bladder are far more tolerant of instru-

previously supposed. It is easy to see that this may lead surgeons to excess in that direction, and so far as there is that danger, we welcome Dr. Reliquet's words of warning; although we cannot thoroughly endorse the precise practice he urges.

*Winters Abroad.* By R. H. OTTER, M.A. London: J. Murray. 1882.—The author's description of a voyage to Australia in a sailing vessel is a faithful picture of the life on board such a ship, and demonstrates the necessity that exists for invalids to travel only by first-class steamers. Well-appointed passenger steamers now cross the ocean in every conceivable direction, whereas sailing vessels have almost ceased to carry anything but their crews and merchandise, and are only in exceptional cases to be chosen for the abode of an invalid. Mr. Otter has formed a most favourable opinion of the climate of Sydney during the cold season of the year, but as the hot months approach he recommends a change to the high-lying towns of Tasmania. His account of Melbourne, Queensland, and New Zealand, as health resorts for invalids, is very valuable, as also are his remarks on the Riverina. Mr. Otter thinks that this part of Australia presents a perfect climate for nine months of the year, especially for persons suffering from affections of the lungs. The climates of Algeria, Egypt, and the Cape of Good Hope are considered with reference to the circumstances of invalids. Regarding the latter, Mr. Otter advises no one in search of health to remain too long in the neighbourhood of Cape Town, and not to take up his abode for any length of time within 100 miles of the sea coast, unless he can be 1500 feet above the sea level. The volume before us is full of practical information and knowledge which too many invalids might otherwise have to gain by dearly bought experience. But our author visited the Cape in 1877, and we have reason to think if he returned there now he might not find the hotel he recommended up to the mark. Information upon these points should be accurate and up to date, otherwise it is best omitted. Passing from a description of the various climates above referred to, our author describes the advantages which Davos affords as a winter resort for a certain class of patients. He thinks "too much is claimed for it by its admirers, and far too little conceded by its detractors." Our space will not permit us to follow Mr. Otter into the data he gives for arriving at this conclusion. We recommend this work to the medical profession, as containing a reliable account of the winter resorts referred to. Medical men have frequently to advise patients on the question of a residence for the winter. A real knowledge of the difficulties to be encountered on the journey, and of the accommodation and kind of place recommended, is therefore of great importance. The fact is, knowledge of this kind can only be properly acquired from personal experience; but next to this in value is information such as that contained in the pages of a work like the one under notice, which is, moreover, pleasant reading. One defect in the book, however, is the absence of an index. We can only hope that Mr. Otter will supply this deficiency in a future edition, and that he will endeavour to complete the valuable work he has commenced, and give us full information regarding the advantages of other winter resorts besides those referred to in this volume.

*Morality.* By MAURICE CHARLES HIME, M.A., LL.D. London: W. H. Guest, Warwick-lane, Paternoster-row. Dublin: Messrs. Sullivan, Marlborough-street; and Marley and Son, Mid Abbey-street.—The little book by Dr. Hime on Morality has very deservedly reached a third edition. Admonition on this subject is much neglected, because it is a very difficult and delicate one to treat, and because parents are sometimes prone to think their children above the danger of falling into the vice of sensuality. The author is eminently adapted to perform the task, owing to his

experience, scholarship, and great zeal. Moreover, in undertaking and accomplishing this work he has shown a good example of self-control and manly conduct—the very principles he tries to inculcate among young men. This, in our opinion, enhances the value of the book; for example is better than precept. The greatest tact is displayed throughout. The reader, if he is influenced at all, can only be influenced for good. Dr. Hime brings to his aid in his pleading with young men the Bible, natural religion, metaphysical reasoning, the teachings of experience, and common sense. These powerful weapons he wields well, and does not refrain from drawing largely on the assistance of other authors. Against this array of revelation, reason, and authority no young man who respects truth can defend for a moment immorality. At the beginning of the second chapter the author ably refutes the argument that "it is a matter of no great consequence whether one exceeds a little in his youth or not." While reading this part of the book we were reminded of the great message of John Knox to men. According to Carlyle, his message was: "Let men know that they are men, created by God, responsible to God, who work in any meanest moment of time what will last through eternity." Dr. Hime does well to lay great emphasis on moderation in alcoholic drinks. When intemperance has lasted any considerable time true repentance is very difficult, almost impossible. This is mainly due to the fact that the brain itself becomes so altered that the higher functions of the mind cannot be put into action. The vice of sensuality diminishes in man as old age comes on, while intemperance increases as long as the victims live and indulge their appetites. Of the two vices, while intemperance is the more persistent, sensuality is the more corrupting and depraving to the mind. Both, unhappily, often go hand in hand. The section on prayer is especially good. Few will feel disposed to doubt the subjective efficacy of prayer, which Dr. Hime has dwelt upon. We should be glad to see this little book in every young man's collection, and especially in the hands of those who, after leaving school, are brought face to face with the temptations of a great metropolis. Any one who carefully studies this work, and who makes use of the four safeguards mentioned by the author, will be well protected against what is the besetting sin of many, and can fearlessly face those who try to argue him into doing what is wrong. The purity of the object and the intrinsic worth of the book ensure, we are confident, a large amount of success.

*The Scientific Basis of National Progress, including that of Morality.* By G. GORE, LL.D., F.R.S. London: Williams and Norgate. 1882.—This little book, dedicated to the Birmingham Philosophical Society, sets forth the power and use of scientific knowledge in all progress, material, mental, and moral. The last section advocates the promotion of original scientific research. It is simply written and fully illustrated by examples; that portion which relates to material progress is naturally the most incontrovertible. If the author seems at times to exalt the claims of natural science to an undue degree, it must be remembered that it has by no means yet met with the universal appreciation which it deserves, and that the doctrine now prevails that if we want anything we must ask for it loudly enough.

We have received a copy of the third edition of the *Improved District Railway Map*, published by Messrs. W. J. Adams and Sons, Fleet-street. It is well and clearly printed and coloured, and the cost is but 6d.; mounted on canvas, 1s. 6d.

**PREVENTION OF SMALL-POX.**—At Willenhall the General Purposes Committee of the Local Board have issued bills advising parents to prevent their children as much as possible from attending the forthcoming wakes, in consequence of many of the show-people coming from Wednesbury, where small-pox is said to be very prevalent.

## New Inventions.

### HIDES' PATENT MOULDED MILITARY AND GENERAL AMBULANCE.

MR. HIDES has very successfully contrived a light serviceable ambulance in which he avails himself of his well-known felt. It consists of a simple wooden frame made of two poles and two cross-bars. Attached to this frame are davits from which is suspended a shell of felt moulded to the form of the back of a well-grown man. Attaching the frame to the davits are Hides' "superb" elastic springs, which are connected with bands of webbing passing under the frame so as to support the main part of the weight carried, and thus guard the felt from wear and tear. The obvious advantages of this form of ambulance are its extreme lightness, and especially the greater comfort and safety secured to an injured person. In a hammock of any kind the person carried rolls down into the bottom; carried on a flat surface broken limbs move and are unevenly supported. But by Hides' contrivance every part of the body is well and equally supported, and the head, arms, and legs in particular lie in troughs so well fitting that they almost answer the purpose of well-adapted splints. The shell is easily unshipped, and the davits removed from the frame, and six frames can then be made to form a crate in which the shells can be packed, so that these ambulances are very easily carried in bulk.

Mr. Hides has carried out the same idea in another direction, in the form of a support or bed rest, intended especially for cases of weak or curved spine. A large piece of felt is moulded to the back of the patient, and when hardened is fitted on to a light frame with springs so as to afford support and pressure to the whole surface of the back of the trunk. This will no doubt be found useful.

### "THE CHEMICAL LUNG."

To the Editor of THE LANCET.

SIR,—As from time to time you have taken great interest in the Chemical Lung designed for the purification of hospital wards, sick rooms, and other collections of foul air, I venture to forward a report of the action of one sent to and experimented upon in the civil hospital at Aden. The following are the words of the medical officer under whose care the experiments were carried out: "The case in which the punkah was tried was that of a man suffering from phagedænic ulceration of the leg, a disease which gives rise to the most foul and offensive odours, so offensive to the other patients in an ordinary ward that it was necessary to isolate him in a small room. It was in this that the punkah was tried with the most beneficial effects, the air being kept odourless and inoffensive so long as the punkah was working; all other disinfectants being discontinued with the exception of a charcoal poultice immediately over the ulcer, but quite incompetent to prevent smell. I consider the punkah a very useful invention and quite able to carry out all that is promised for it. For infectious disease hospitals, for night wards and isolating rooms of ordinary hospitals, it might with advantage be adopted. The best test I know to which it could be subjected would be to try it systematically for a whole year in the night wards of one of the big Indian gaols, the mortality of which is unequalled in any community throughout the civilised world. This mortality arises doubtless from overcrowding, theoretically correct as the linear measurements and cubic feet of air allotted may be." I feel that no comments of mine are needed upon the above; I would only state the results of an experiment carried out by myself in a room crowded with twenty couples, dancing for five hours, the windows being shut, in the middle of last June. The punkah kept the air of the room deliciously cool and pure the whole time.

I am, Sir, your obedient servant,

RICHARD NEALE, M.D. Lond.

Boundary-road, South Hampstead, Sept. 19th, 1882.

---

# THE LANCET.

---

LONDON: SATURDAY, SEPTEMBER 16, 1882.

PROBABLY no official reports emanating from the Local Government Board have ever been more anxiously awaited than those on the Use and Influence of Hospitals for Infectious Diseases by Dr. THORNE THORNE and Mr. W. H. POWER. The need for definite information on this subject has been brought home to everyone interested in the sanitary condition of the metropolis by the lengthy and costly legal proceedings which have already resulted in the closing of one large institution for the reception of infectious persons, and in the limitation of the usefulness of others. Nor is the subject one that concerns London alone, for within recent years a number of hospitals for infectious diseases have sprung up in all parts of the country, and communities have been taught to regard such institutions as helpful in a large degree, if not absolutely necessary, for the prevention of the extension of the class of disease for which they have been erected. The fact that the use of these hospitals might be attended by any drawback was so little believed by the members of our own profession, that nothing short of the Attorney-General's masterly management of the case against the hospital of the Metropolitan Asylums Board at Hampstead could have succeeded in arousing suspicion that the full influence of such institutions upon the neighbourhood surrounding them might not be fully known. But the story which Sir FARRER HERSCHELL first told concerning the Hampstead Hospital was soon told again for other hospitals of the Metropolitan Asylums Board, and thus the subject attained a degree of importance which it was impossible not to recognise.

The relations of the Local Government Board to these and similar institutions in all parts of England and Wales made it incumbent on that Board, for its own information, to learn definitely their effect on the neighbourhoods in which they were situated. In the chapter in which Dr. BUCHANAN introduces the reports of Dr. THORNE and Mr. POWER to his Board, he states that a return made in 1879 shows that "296 authorities had arrangements of one sort or another in hospitals of their own, or by an understanding with their neighbours, for the reception of infected persons who could not be treated in their own homes with safety to other people"; and, referring to the fact that sanitary authorities who might be wishful to provide hospitals were frequently finding themselves hindered by a number of difficulties from carrying out their intentions, he says it was seen that the Board could with advantage collect, for the assistance of some sanitary authorities, the experience of other authorities who had made hospital provision, and could learn whether there was any ground for the fears which were entertained by landowners and others, and what were the conditions for removing or reducing any real danger found to exist. To this object Dr. THORNE'S labours were devoted, and during 1880 and 1881 he inspected seventy hospitals for infectious disease, the history of which occupies the greater part of the volume now before us.

We shall reserve for further and fuller discussion the many important points treated in Dr. THORNE'S report, but we may state briefly that he gives evidence of the value of hospital accommodation, particularly at the beginning of epidemics. His report also deals with hospitals under all conditions, and includes a short account by Mr. SHIRLEY MURPHY of an inquiry into the amount of prevalence of fever in the neighbourhood of the London Fever Hospital. Dr. THORNE found that, apart from spread of infection due to faulty hospital administration, there was no evidence of any of the infectious fevers other than small-pox having occurred in the neighbourhood of infectious hospitals; and with regard to the latter disease, in only two instances were there grounds for suspecting that any such occurrence had taken place. But Dr. THORNE, during the course of his inquiry in the provinces, had met with no recent instance in which a large aggregation of small-pox cases had occurred in any infectious hospital in the vicinity of dwellings, and to this extent he regarded his inquiry as to the influence of such hospitals for harm as incomplete. Under these circumstances the inquiry was extended to London, and Mr. W. H. POWER was associated with Dr. THORNE for the purpose of ascertaining the experience available as regards the Fulham Hospital. And it is in Mr. POWER'S report on the influence of the Fulham Small-pox Hospital on the neighbourhood in which it is placed that the more immediate interest chiefly centres.

We cannot do better than follow the report itself in the history it gives of this institution and its surroundings. The hospital occupies a site which, as Mr. POWER says, from the view-point of medical knowledge at the time of its selection, was singularly free from objection, for, with few exceptions, there are not within 500 feet of the limit of the hospital grounds any inhabited dwellings. As regards traffic routes, the hospital is also isolated, for by two roads alone can ambulances reach it. At the time Mr. POWER began his inquiry, small-pox, although prevalent in the East-end of London, had not invaded the surrounding parishes of Fulham, Chelsea, and Kensington; but the hospital had, on December 13th and 14th, 1880, received from the Homerton Hospital forty persons convalescent from small-pox, and it continued to receive such cases until Jan. 17th, 1881, the date at which Mr. POWER'S labours began. By this time 110 convalescents had been admitted. Meanwhile, fifty-five acute cases had also been received, of which only five came from Chelsea, Fulham, and Kensington. At this moment, therefore, there was really no reason for the people of the neighbourhood to visit the hospital, a point upon which Mr. POWER properly lays great stress. He immediately, for the purposes of comparison, selected a special area of a circle round the hospital of one mile radius. That his arrangements for obtaining information of cases were most thorough is best made evident by the fact that a subsequent house-to-house inspection brought to his knowledge only half a dozen cases which had not been previously reported. The account which he gives of the occurrence of cases in the neighbourhood of the hospital may therefore be considered to include all such attacks—a matter of very considerable importance. After

the opening of the Fulham Hospital no person in the three parishes of Chelsea, Fulham, and Kensington was attacked in either of the fortnights ending the 11th and 25th of December, but by the 22nd January eleven cases had occurred, all in separate houses, and seven within the special area. An inquiry into the movements of these seven persons showed how two of them had contracted the disease; while another two, although not known to be exposed to small-pox, had worked in the East-end where the disease was prevalent; but for the remaining three no explanation could be found. In the next fortnight ending February 5th, there occurred a general outburst of small-pox in Chelsea, Fulham, and Kensington, the fresh cases numbering sixty-seven, of which forty-seven were situated in the special area, while the remaining eleven were within a further half-mile of the hospital. When households are considered, the disease is found to have invaded fifty-six fresh houses during the fortnight; of these forty-one were within the special area, and eleven others within a further half-mile. But a curious limitation of the outburst with regard to time was observed. Of sixty-two persons who were attacked during the previous fortnight, four only began to be ill before January 26th, while in the four succeeding days forty-two persons were attacked, thirty-two of whom lived in the special area, and eight within a further half-mile. The forty-two persons must therefore have contracted their disease at a time when not more than four cases of small-pox had occurred in the special area, and eight only in the whole of the three parishes. An inquiry into the precise doings of the forty-two persons attacked during a fortnight before their illness began showed that in nine cases only could evidence or reasonable suspicion be found that the sufferers had had personal relation, direct or indirect, with a case of small-pox. Mr. POWER admits that up to this stage there is no evidence against the hospital, and if it was to be held responsible for the special prevalence of small-pox in its neighbourhood on this occasion, it must be shown that there was a similar distribution of cases each time the hospital was used in past epidemics. With a view to testing this point he divides the time since the hospital was opened, in March, 1877, into five epidemic periods, and he calculates from the number of houses from which patients were admitted into the Metropolitan Asylums Board Hospital, the amount of prevalence of small-pox in each period in the three parishes, in the special area, and in other parts outside the special area, and for the purposes of comparison he takes a period of one year before the hospital was opened, and shows the distribution of cases of small-pox during that period in the three areas already mentioned. It is unnecessary here to say more than that Mr. POWER has taken pains to eliminate any possible source of error owing to changes of population in these areas—indeed, so far as any changes have taken place, they would tend to make less obvious the different amounts of prevalence in them; nevertheless, in each epidemic period he finds the distribution of cases following the same law—namely, that for every 100 houses in each area a far greater proportion were invaded in the special area than outside, while before the hospital was opened the opposite was the case.

Another point was observed in each of these epidemic

periods, which is equally instructive. In each period, without exception, an outburst of disease occurred in the neighbourhood of the hospital. About a fortnight after it contained as many as from thirty to forty acute patients—a length of time corresponding with the incubation period of small-pox; but in the second fortnight a diminution in the number of fresh cases round the hospital invariably took place. The number of convalescents in the institution appeared to have in no single instance any influence in causing disease. A further division of the area round the hospital into rings of a quarter of a mile invariably showed in each epidemic a decreasing incidence of disease the more distant the rings were removed from it. Nor were the cases distributed along the chief lines of traffic, but they were scattered equally over the area surrounding the hospital in a manner that entirely negated the supposition that they might be due to personal communication. Mr. POWER made this point a matter of painstaking inquiry; he informed himself of every movement of each member of the hospital staff at the time at which infection must have been received by the persons who were attacked in the fortnight ending February 5th, 1881, but failed to find the least relation between the two. Every detail of the hospital administration was examined, but with only negative results. Having in view the distribution of cases and the circumstances connected with their appearance, he is driven to the conclusion that they must be due to atmospheric communication with the hospital.

It may be argued that until the same story can be proved for other small-pox hospitals Mr. POWER's conclusions must be accepted with reserve; but it must be recollected that a possibility of error of this character has been guarded against by his investigations into the behaviour of five separate epidemic periods, and that the occurrence of disease has on each occasion appeared to be governed by exactly the same laws. That he has dealt most fairly with his subject must be admitted; indeed, he speaks of the reluctance with which he has felt compelled to come to his conclusions; but with such evidence it is impossible not to accept, with Dr. BUCHANAN, that "the Fulham Hospital, with all its advantages of site and construction, has, by dissemination of small-pox material through the atmosphere, given rise to an exceptional prevalence of small-pox in its neighbourhood.

We cannot at this moment enter into Mr. POWER's speculations as to how small-pox matter came to be disseminated through the atmosphere. This raises a large question, and must be reserved for a further notice; but we cannot leave the present one without bearing witness to the very great ability with which he has dealt with a most difficult question. We find on every page of the report before us the same precise observation and thought as that which characterises his previous work, enabling us to accept with more readiness this last addition to our knowledge of the behaviour of small-pox.

THERE is no more remarkable and, in a way, mysterious, phenomenon of modern times than the influence of the press. We say of modern times, but it is probable that the particular form of moral or social force to which we allude may have asserted its influence and performed its share in the work of progress thousands of years ago, seeing that the life

and history of at least one newspaper published in China dates from a period—almost ages ago. However this may be, it cannot be doubted that “the press,” properly so called, that is to say, the journalistic or news communicating development of literature, constitutes one of the most potent controlling authorities of our national life, if indeed it be not the pivot and centre of union and self-government. It is certainly the safeguard of our liberties.

In what the power of the press actually consists, it is not easy to determine. Political and social economists recognise the power, but they have never been able to define it. Probably several elements combine to produce the result. First, there is the impression wrought on the mind by the fact that those who read are in the position of the instructed. There is some source of information to which they have not direct access. The press stands to them in the relation of a teacher, and the mind always, though insensibly, it may be unwillingly, bows to the possessor of greater knowledge than its own. There is clearly something in this; even a stranger or worthless loungee is for the moment invested with peculiar distinction in any community to which he brings news. Secondly, growing out of this prestige which belongs to the press as an oracle, there is the claim to respect which it can and does successfully put forth as a professional enterprise. As a department of industry journalism has not lagged in the march of intellectual advancement. If there be, as undoubtedly there is, a broad line of distinction between journalism and literature, the former has been making excellent progress as far back as we can trace its history. In truth it has outrun literature proper; and whereas the books of to-day, except for the recently acquired information they embody, are no better than, if as good as, the works of those who wrote generations ago, contemporary newspapers have been incomparably improved, both in matter and style, within living memory. Men of average ability, education, and earnestness devote their energy to the collection of news and the production of newspapers, and it must needs be that the claim to authority which grows out of special work of any and every kind is recognised by public opinion. Whether, on the whole, public opinion is not outgrowing the state of pupillage, in consequence of the celerity and completeness with which the data upon which the journalist bases his conclusions are presented to the public, so that the reader is nearly, if not quite as well able to form a judgment as his professional instructor, is a question we will not now attempt to discuss. Suffice it to have recalled to the mind of the reader the leading facts as to the influence of the press, and suggested certain lines of thought, which he may work out for himself, and which will help to prepare the way for that special view of this interesting subject, which we are chiefly anxious to present and enforce.

There is an evident disposition on the part of “authorities” generally to limit the freedom and if possible to reduce the power of the press. We see indications of this intent everywhere. The censorship of news, and now the limiting of news-agents, established and enforced “by authority” during the present campaign in Egypt, is a remarkable instance of the working of this intent. The exclusion of reporters from executions we take to be another. And the endeavours of corporations to suppress the criticism of

professional journals of health and hygiene on the sanitary condition of important towns may be also mentioned as instances and evidences of the tendency to limit the power, and if possible restrain the activity, of an agency which has hitherto done excellent service in the cause of right and freedom. By bringing facts to light and pointing out their significance, the press has done more than any other agency to help forward the van of progress and intelligence, and to make and keep peoples free, while despots who reigned by the aid of darkness and ignorance have been overthrown. In matters great and small—political as regards the State at large, or politic in respect to smaller areas and sections of the population—social, commercial, scientific, and sanitary,—in all departments of interest and enterprise, the power of the press has been manifestly exercised in the interests of the people. We think the time is approaching when the whole press and the entire community will need to combine if the blighting and crippling influence of officialism is not to be allowed to efface those liberties which the press has won, not for its own sake alone, or even principally, but for the people, by whose authority and for whose benefit the press exists.

Within the boundary line of our own experience as a journal devoted to the public service in the promotion of health and the limitation and remedy of disease, we have had notable proofs of the “power of the press,” and in every instance our own interest has been proved to be identical with that of the profession and the public. Since the late Mr. WAKLEY founded THE LANCET to protect the rights of the public, and to assert the rights of the profession against encroaching corporations, our enterprise has been specifically one of reform. We have not feared to expose abuses or to strive for the removal of obstacles to the progress of science and health. A long score of successes in this enterprise has been our reward, and we shall not flinch from prosecuting our work on the old lines and with the same energy in the future as in the past. Meanwhile we are certainly of opinion that the moment has come when the press generally ought to assert itself, and when the position gained by journalism should be resolutely defended. If it is not to be *free*, it had better cease to exist. It is scarcely possible that such a calamity should befall so vital an organisation, but if it did ever happen that authorities obtain control of the journals so that only selected news appeared in their columns, and adverse criticism were repressed, there would at once be an end of all influence and usefulness. A free press is necessary to the freedom of the whole nation and every section of the community. An irresponsible press—albeit that would be incomparably better than a press in chains or the creature of authority—no one desires.

It seems to be forgotten, or intentionally shut out of sight just now, that a natural censorship of the press exists, and must ever exist, in the restraining influence of public opinion. If a journal were found to abuse its power it would not long retain the influence it misused, and great would be the fall of it. The State and the law cannot, of course, afford to leave everything to the arbitrament of public opinion, but some respect might fairly be shown to

that tribunal, which, after all, as regards every moot question, not excepting that of Government itself—which in this country be it remembered is *self-government*—constitutes the court of final appeal. That court may be tardy in its proceedings and slow to express itself, especially in reference to matters relating to its own authority, but when deliverance is given it will be shown that the power exists by which the judgment pronounced can and must be enforced. At the same time, as we have said, the press owes it to its own character as an independent authority to affirm its rights, in so far as these are legitimately based on public opinion. The public *must* be promptly and fully informed, however much the spread of intelligence may inconvenience those who, tricked out in a brief authority, strive to use it as though it were their own. Moreover, the press must be free to speak its mind. This proposition may not at first sight appear so obvious as that previously stated. It may seem that the public, having got the facts, might be left to draw their own conclusions. In some connexions, doubtless, this is true; but if it were true of all, there would be an instant end of professional criticism. For the interpretation of facts special knowledge is generally necessary; when the facts are special, it is imperative that there should be special knowledge to appraise, collate, and explain them. In the absence of such a service, the significance of many facts would be overlooked until it was too late to profit by its recognition. This is why we claim freedom—with responsibility—for professional journalism, and particularly for the special journalism of a profession. If this freedom be not secured to the press, its power will be sacrificed, and it is difficult to see what other force can be found to replace it as a perpetual check on the neglect and wrong-headedness of “authority” and “officialism,” by which the people are in continual peril of being misled.

THE prolonged public inquiry which has been held at Norwich by the Inspectors of the Local Government Board, Mr. HENLEY and Dr. AIRY, has elicited a large amount of information with regard both to the death of certain children as the result of erysipelas following on vaccination, and to the injury of others. In all, thirteen cases were submitted for inquiry, but three of the children in question, having been vaccinated privately, were not deemed to fall within the scope of the investigation, which had reference to the effects of vaccination as carried out at the public vaccination station in the city. The majority of these children have unquestionably suffered from erysipelas after vaccination, and Dr. GUY freely admitted that in his opinion this result was in some way connected with the performance of the operation. The main contention of those by whom the inquiry was brought about has been that the infection leading to the erysipelas was inoculated with the lymph, and hence that vaccination as such was responsible for the death and injury resulting. Until the full official report of the proceedings appears it will be impossible to express a final opinion on this part of the subject; indeed we doubt very much whether the facts elicited at the public inquiry are sufficient to clear up such a point. But before the public inquiry was commenced, a careful medical investigation of the circumstances had been made by Dr. AIRY; and this investigation, unhindered by

the laws of evidence and other legal technicalities, has doubtless elicited points of medical interest which could hardly have been ascertained with the requisite scientific accuracy by the ordinary legal process of examining and cross-examining witnesses. But even at this stage of the proceedings some points of considerable interest have transpired with regard to this subject. The first of these is that in some of the children the commencement of the erysipelas was observed within some twenty-four hours of the performance of vaccination, in others not till after the expiration of eight days from the vaccination. If infective material producing like inflammatory results had been contained in the lymph, the interval between its inoculation into the system and its manifestation could hardly have varied so greatly. And again, the lymph used does not appear to have been all taken from the same vaccinifer; all the vaccinifers whose lymph is alleged to have produced erysipelas have turned out to have been healthy children; and not only so, but of the children vaccinated with the same lymph some few only had erysipelas, whereas in the remainder the process of vaccination was from the beginning to the end quite natural. If therefore we assume, as we fear we must, that there was relation between the vaccination and the erysipelatous inflammation, we are thrown back not so much on the lymph as the cause, as on some accidental poisoning occurring in connexion with the process of vaccination. Hence doubtless the minute inquiry as to the method in which Dr. GUY performed his duties as a public vaccinator, and which elicited the facts that his lancets were regularly washed between each vaccination, that they were frequently reground and polished by a surgical instrument maker, and that Dr. GUY has several times received a Government grant for the efficient manner in which he has performed the various duties attaching to his office. It is true that much was made of the circumstance that Dr. GUY did not proceed to strip the children before he vaccinated them; but quite apart from the fact that it has never been suggested that the children who suffered from erysipelas were otherwise than healthy at the date of vaccination, we are bound to say that the “Instructions for Vaccinators under Contract” nowhere appear to us to refer to stripping as necessary, and that in nine cases out of ten the very necessary regulations calling for examination of certain parts of the body, and especially of the folds of the skin, can be carried out without resort to any such process. But the same “Instructions” contain a caution which is especially noteworthy in connexion with the cases under investigation, and that is, never to vaccinate, except in cases of necessity, “where erysipelas is prevailing in and about the place of residence.” Erysipelas has been prevalent in Norwich quite apart from its incidence on children who were vaccinated at the public station; and the demand that certain cases vaccinated by private practitioners—and this with other lymph than that used by Dr. GUY—should be included in the inquiry, points to the fact that the infective material leading to the erysipelas was of wider distribution than was at first anticipated. Dr. GUY, in his evidence, admitted that towards the end of June, just after the period involved in the inquiry, he became aware that a slight epidemic of erysipelas was prevailing at Norwich. Now, children on the day of vaccination and on the day

when their vaccine vesicles are opened by a lancet for the vaccination of others, present wounds which, though of a very trivial character, afford a means by which such a poison as erysipelas can be received into the system. This poison may have been conveyed by someone, in clothing or otherwise, to the vaccination station; it may have been brought into contact with the children after returning to their homes, some of which were far from healthy; and it certainly seems to have infected some vaccinated infants who never went to the public station at all. Pending the publication of fuller details, we avoid arriving at a conclusion as to the exact channel through which the infection was conveyed, but, by a perusal of the evidence, we are confirmed in our opinion that the lymph of healthy vaccinifers does not of itself produce erysipelas, and that if erysipelas be prevalent in a district, it may by obscure and perhaps as yet unrecognised channels find its way into the human system through the medium of the smallest wounds. Erysipelas has more than once followed in the track of surgical operations which have been necessary to the saving of life, but instead of discrediting these operations on that account, every effort has been made to eliminate even the possibility of so grave a complication. No operation ever yet saved so many lives as have been spared to us by vaccination, and if the inquiry held at Norwich has the effect of disclosing some source of danger, hitherto undetected, with which even this trivial operation may under certain circumstances be associated, the cause of vaccination will, as its result, be in the long run promoted, and not retarded.

THOSE who would intelligently grasp the questions involved in Medical Reform should begin their study of the Blue-book of the Royal Commissioners by reading the paper by the Secretary of the Commission, Mr. WHITE, entitled "Statement in regard to recent attempts at Medical Reform." Mr. WHITE carries his readers back to the Medical Act of 1858, and the purpose of those who passed it. He says the Act was the result of a general desire to establish a central authority in the medical profession; to institute a Register of its qualified practitioners; to impose a sufficiently uniform test of qualification before names were entered upon such Register, and to have a National Pharmacopœia. He shows of course that the Council, consisting of twenty-four eminent men, and with an income of many thousands a year, has done some good; that it has produced a Register, that it has published a fairly good National Pharmacopœia, that it has improved preliminary education, and exercised an influence for good on the several licensing bodies. The Act of 1858 "broke down the territorial privileges of the licensing bodies, and made a licence valid anywhere in the United Kingdom. It further unified the profession by placing the entrances to it under the guardianship of one General Council." With this statement of the good results of the Act, occupying two pages out of sixteen, Mr. WHITE'S illustration of the good working of the Medical Act ceases, and he begins a most striking illustration of the faults and defects of the Act and of the Council which it created, and by which it must be mainly judged. This illustration is given obviously with so little design of injuring the Council, and with such simplicity of detail and history as to be the most convincing proof, if any

were needed, in addition to the evidence now before Her Majesty, of the absolute necessity of a Council differently constituted from the present, if the work of medical education is to be advanced, and if medical boards are to be delivered from the great stigma of acting unequally in the three divisions of the kingdom. Mr. WHITE says: "But it soon became evident in many ways that the Act.....was failing to realise all the hopes of its promoters, or to satisfy the demand for medical reform. Fault was found with the working of particular institutions; defects were shown in the general system established by the Act. The diplomas issued by some of the bodies were said not to prove that amount of fitness for practice which they professed to guarantee. The examinations on which they were granted were pronounced insufficient, and the machinery provided by the Act for putting a stop to such laxity of licensing, when brought to the test of experience, was declared to be ill-constructed. For the Medical Council had been given by the Act no direct control of the licensing bodies," &c. The Council had of course its defence and explanation ready. "But whatever the Council's justification, the fact remained that some of the bodies were generally believed not to examine thoroughly in the subjects in which they licensed. Further, the diplomas were nearly all 'half diplomas,' and the provisions of the Act for encouraging the voluntary combination and co-operation of the bodies in giving complete diplomas were not satisfactory. Even the three bodies which did so combine continued to grant their half diplomas separately." Then comes the great demonstration of the Council's inadequacy to deal with such evils. It became alive to them as early as 1867, and for several years, under the lead of the lamented PARKES, and stimulated from without by Mr. SIMON, passed resolutions and adopted reports setting forth the inequality of examinations, and the *halfness* of diplomas. In 1870, by a majority of seventeen to one—the dissentient being Sir DOMINIC CORRIGAN,—the Council passed a resolution in favour of the establishment of a joint examining board in each of the three divisions of the kingdom. So earnest and unanimous was the Council then, that on its recommendation the Government brought in a Bill making a single board in each division of the kingdom compulsory. Since then the Council has changed its own mind. Under the influence of Dr. WOOD—according to Mr. WHITE—but according to our view, under the influence of a much more dominant intellect and character, that of Sir ROBERT CHRISTISON—all Scotland backed out of its support of the Conjoint Scheme. Ireland followed suit. So that whereas in 1870 only Sir DOMINIC CORRIGAN—a free lance by general consent—voted against compulsory Conjoint Boards, in 1878 ten voted against them. Of the ten, nine represented medical authorities—namely, all the Scotch authorities without exception, and all the Irish authorities except the Apothecaries. The tenth opponent of the resolution was the Crown Nominee of Scotland. On the showing of Mr. WHITE, then, on the main question of medical reform, the Medical Council is a house divided against itself, and too much concerned with local interests and views to put the question of licensing medical examinations on a national basis. In plain terms, the history of medical reform in the last fourteen years has been a history of failure—a history of nineteen bodies out

of sympathy with the profession, several of which are superfluous, striving to perpetuate themselves and all their individual privileges, without reference to public advantage, and the question of justice to those on whom exacting examinations and fees are imposed. In the next few weeks we shall try to give our readers some account of the evidence of the witnesses before the Commission on the principal questions involved in medical reform, and which must soon engage the attention of Her Majesty's Government.

SOME experiments carried on during the past year by Professor H. NEWELL MARTIN, and described by him in a paper published in the Transactions of the Medical and Chirurgical Faculty of the State of Maryland, appear to be of great value in determining the effect of variations of blood-pressure upon the pulse-rate. When it was shown that by increasing the pressure in the arteries the pulse was slowed, it was assumed that the greater force to be overcome by the ventricle entailed a longer systole, and that the result was the direct effect of the pressure upon the muscular tissue of the heart. The discovery that there is in the medulla oblongata a cardio-inhibitory centre which is stimulated by increased blood-pressure, and also a cardio-accelerator centre stimulated by lessened blood-pressure, and that the effects described by MAREY were to be traced to the action of these centres, rendered necessary further investigations to determine whether variations in blood-pressure have any direct influence upon the pulse-rate. The results obtained by such trustworthy observers as HEIDENHAIN, LUDWIG, v. BEZOLD, and others, have been found to vary so greatly that no reliance whatever can be placed upon them. Professor MARTIN has, by eliminating apparently every source of error, arrived at constant and decided results, which also serve to explain the contradictory statements of previous observers. His mode of procedure is as follows. The animal—a dog—having been tracheotomised, placed under curari, morphia, or chloroform, the common carotid arteries are tied, and cannulas placed in their central end. Artificial respiration is then established, the front and sides of the chest removed, and the two subclavian arteries are tied below the origin of their first branch. One limb of a curved metal cannula is then introduced into the aorta, and thus all circulation through the systemic arteries except the coronaries is blocked. The two venæ cavæ and the vena azygos are tied, and a large tube in communication with a flask of defibrinated blood is introduced into the superior cava on the cardiac side of the ligature. The carotids are then opened, and all the blood in the heart and lungs is washed out by the defibrinated blood. While this is being done a thermometer is placed in the left subclavian artery. The animal is then transferred to a warm moist chamber; the superior cava is connected with a MARIOTTE'S flask, from which defibrinated blood under a known and easily regulated pressure enters the vein and the right auricle. The blood flowing from the aorta is collected in another similar flask. The venous pressure can be altered by raising or lowering the MARIOTTE'S flask, and the arterial pressure can be increased or diminished by elevating or lowering the exit point of the tube connected with the aorta. All being ready, arterial pressure, as measured in the carotid, was varied between the limits of 40 mm. and 210 mm. of mercury,

and tracings taken of it and of the pulse-rate. Although this was done repeatedly, and both suddenly and gradually, it was found to in no way influence the pulse-rate, which gradually and uniformly fell. If the venous and arterial pressure were coincidentally greatly increased, the character and rapidity of the pulse were profoundly altered. If while the arterial pressure was kept constant, the pressure in the vein was altered by raising or lowering of the MARIOTTE'S flask, in the same way the pulse-rate underwent no change. The experiments, which were often repeated, curari, morphia, and chloroform being used in turn, so as to exclude any effect of these agents, show that alterations in the blood-pressure, either arterial or venous, do not directly affect the pulse-rate.

In a further series of observations Professor MARTIN maintained the blood-pressure in both vein and arteries at a constant level, but varied the temperature of the defibrinated blood supplied to the heart, and he found that the pulse-rate rose with every increase in the temperature of the blood, and fell as it cooled. The fact that the pulse quickens with rise of temperature has of course long been familiar, but it was explicable upon two theories. The hot blood might act directly upon the tissue of the heart, or, paralyzing the cardio-inhibitory centre in the medulla oblongata, influence the heart indirectly. MARTIN has now shown that a dog's heart, completely liberated from all possible influence of nerve centres outside itself, slows its rate of beat from minute to minute, as the temperature of the blood sent through the coronary artery falls, and quickens its beat as the temperature rises; and it has yet to be proved that the increased frequency of the pulse in the febrile state is in any way dependent on paralysis or excitation of the cardio-inhibitory or cardio-excitator centres in the medulla. In attempting to find the extremes of temperature compatible with cardiac life, it was found that a dog's heart would beat regularly and slowly at 26° C., and regularly, but rapidly and feebly, at 41° C.

Professor MARTIN shows how his investigations explain the results of other observers labouring at the same problem. For example, v. BEZOLD in some experiments on curarised rabbits, with all extrinsic cardiac nerves divided, increased the blood-pressure in one of three ways. He either raised the hind part of the animal, and so pressed blood from the belly to the heart; or, after opening the chest, he clamped the aorta just beyond the origin of the left subclavian artery; or he injected into one carotid calf's blood carefully warmed to 38° C. By each of these methods not only was the blood-pressure increased, but the temperature of the blood in the heart was raised, and so the increased frequency of the pulse was produced. In the first experiment, abdominal blood, nearly 2° C. hotter than that in the external jugular vein, was forced back to the heart in excess. In the second experiment, when the aorta was clamped, the blood forced into the aorta returned from the head and fore limbs much faster than before, and a larger amount of blood flowed through the lungs in a given time, and as only the same amount of cool air was pumped into the lungs by artificial respiration, the blood was much less cooled; or, in other words, the blood then reached the coronary vessels hotter, and so raised the pulse-rate. It has been shown that one effect of curari on the dog is to lower the

temperature of the venous blood 3° C. Assuming that the effect is the same in the rabbit, the calf's blood at 38° C. introduced into the carotid artery in the third experiment, was 3° C. hotter than that in the veins, so that here again the means taken to raise the blood-pressure also raised the blood-temperature. Professor MARTIN has been successful in eliminating this source of error, and has apparently reduced a complex problem to its simplest conditions, and has succeeded in obtaining results of great value and importance.

A RECENT number of the *Saturday Review* in commenting on Professor ATTFIELD's address at Southampton, remarks that it is astonishing how little suspicious even suspicious people are of the drugs which they take when they are ill. They are quite alive to the prevalence of adulteration in other trades, but they will swallow medicines hastily fetched from the nearest chemist's without so much as a misgiving that they are not in all respects what they profess to be. Yet in nothing is adulteration so easy or so profitable as in drugs. The taste will sometimes assist in its detection in articles of food, but in medicines it avails us nothing. Genuine drugs are often very costly, so that the gains derived by substituting other substances for them are great. In no trade are the effects of adulteration so disastrous as in that of the druggist. Adulterated food or drink provokes disease, but the adulteration of a drug snatches away the last lingering hope of recovery from the dying patient. How often is death attributed to the virulence of the disease, or perhaps to want of skill on the part of the doctor, when in reality it is attributable to the use of worthless medicines. The doctor ordered the appropriate remedy, and if actually administered it would in all probability have checked the course of the disease. But what was actually administered was not the remedy at all, but a counterfet of it, and though the patient did not detect the difference, the disease did, and the patient died. How to ensure that drugs shall be what they profess to be is one of the most important problems in practical medicine, and one to the solution of which few contributions have as yet been made.

The strictures of our contemporary are severe but they are just, and we cannot be sufficiently grateful to anyone who calls public attention to a matter which affects us so closely. But it is probable that the *Saturday Review* does not know and even doctors themselves do not realise the extent to which the practice of "sophistication," as it is conventionally called, is carried on. Much information may be derived from a report on the Deteriorations, Adulterations, and Substitutions of Drugs presented to the American National Board of Health. Powdered drugs, we are told, are almost universally inferior in quality, and it is well known that powders are commonly offered at the same price as the crude drug, notwithstanding the cost of labour and the loss occasioned in drying and powdering. Many of the officinal preparations are of such a character as not to bear very close scrutiny. Tinctures vary materially in quality, and are frequently made of inferior strength both as regards drug and menstruum, in order that they may be sold at a lower price. From the report to which we have referred it appears that even crude drugs are frequently adulterated. For example, much of the aconite root sold is partially or entirely tasteless, being first ex-

hausted of its alkaloids and then redried. Of different samples of arnica examined one contained fifty per cent. of the true drug, another only ten per cent., whilst a third contained none at all. Sarsaparilla is found to be frequently adulterated with nut-galls, ipecacuanha, matric-stems, paper, bark, straw, and belladonna leaves. All the high-priced drugs are especial objects of adulteration. Of three specimens of santonine submitted to analysis, one contained mica in large quantities, another twenty-two per cent. of boracic acid, whilst the third consisted almost entirely of picric acid. We know of a case where a patient suffering from rheumatic fever was given powdered sugar flavoured with quinine in place of the salicine prescribed. Quinine itself is most extensively adulterated; in one glaring instance finely picked cotton was introduced into the bottles in order to increase the bulk. It is an undoubted fact that many specimens labeled "sulphate of quinine" are destitute of the slightest suspicion of the presence of any alkaloid derived from cinchona bark. In a leading Continental city there was until recently an extensive establishment devoted entirely to the manufacture of spurious drugs, their preparation giving evidence of consummate skill. This is a subject of the utmost importance, affecting not only the honour of our profession, but the welfare and safety of thousands whose lives are entrusted to our care. No wonder that in certain quarters there is a growing disbelief in drugs when such pernicious practices are resorted to, and adulteration becomes the rule and not the exception. It is a matter calling for strict and impartial investigation, and our thanks are due both to Professor ATTFIELD and our contemporary for having brought the subject so prominently before the public.

WE publish in another column the report of the conviction of an unqualified practitioner for forging a death certificate in the case of a patient whom he had attended. Last week the Coroner for Middlesex held an inquest at the Coroner's Court, Islington, on a man who was seen by Mr. DUDLEY POWER, an unqualified practitioner. Mr. RICKETTS watched the case for POWER, and Mr. PRIDHAM for the Medical Defence Association. POWER seems to have mistaken the nature of the case, and to have diagnosed drunkenness instead of pneumonia, which was afterwards diagnosed by Mr. ROWNTREE, a Poor-law medical officer, and found, post mortem, by Dr. HERBERT JAMES CAPON. Mr. ROWNTREE said that 90 per cent. of such cases, under proper treatment, would recover. The jury, after deliberating twenty minutes, returned a verdict of "Manslaughter" against Mr. POWER for feloniously killing the deceased. The coroner issued his warrant for the accused to take his trial on that charge. The bail was fixed at two sureties in £100 each. It is noticeable that the wife of this unfortunate patient was advised to go to a public-house and get a letter for threepence for a dispensary kept by Mr. POWER. No letter was obtained, but Mr. POWER prescribed.

Yet another case in point. At Worship-street on Sept. 8th, Mr. UPFIELD, assistant to Mr. W. H. DRY, M.R.C.S., of Kingland Dispensary, Kingland-road, was summoned, together with Mr. DRY, before Mr. BUSHBY, at the instance of the Medical Defence Association, charged with having given a false certificate or declaration concerning the death of one HENRY JAMES AULT. Mr. PRIDHAM, solicitor, pro-

secuted for the Association. He said the summonses were taken out under the Births and Deaths Registration Act, 1874, section 40, subsection 2, and each of the defendants was liable to a penalty of £10. In the case of the death of any person who had been attended during his last illness by a registered medical practitioner, it was provided that a certificate of the cause of death should be given by this practitioner. The defendant, UPFIELD, resided at the Dispensary, 235, Kingland-road, where he carried on the business for Mr. DRY, who was a duly qualified medical practitioner, and whose name was used in connexion with it. Mrs. AULT, the mother of the deceased child, went to this dispensary, and UPFIELD attended the child up to within a short time of its death, and to him they paid the fees which would be paid to a duly qualified medical practitioner. The child died, and UPFIELD, on being asked for a certificate, gave one to Mr. EDWIN AULT, the child's father, beginning, "I hereby certify that I attended HENRY JAMES AULT," stating that the child died of scarlatina and diarrhoea, and signed "W. H. DRY, M.R.C.S., L.S.A." Mr. DRY admitted he had never attended the child at all. Mr. BUSHBY said it did not appear that UPFIELD had represented himself to be a qualified practitioner, but at the same time the Act had been deliberately broken by both defendants, and he should impose the full penalty of £10 in each case.

It is amazing, after what happened at the last meeting of the General Medical Council, to find either a practitioner or his unqualified assistant placing themselves in such a position as that of Mr. DRY and his assistant in this case. It is probable that Mrs. AULT was under the delusion all the time that the person in attendance was Mr. DRY. It is a painful fact that, under the sham dispensary system, there is a rapid change of assistants and principals. The poor people who go can only assume that the person they see and who poses as a medical man is the principal and a qualified medical man. The deception practised is a very serious one, especially when death and grave diseases are involved. It is discreditable to our system of public prosecutions that these cases are not much more extensively exposed than they are. They cannot much longer go on without exciting the attention of the Public Prosecutor, not in London alone, but in the provinces. Why should juries and a Medical Association have the sole labour of investigating a system like this? Meantime, in the name of the public, and especially the poor, we cannot but feel grateful to the Medical Alliance Association for so effectively bringing to light an indefensible system of medical practice with which no medical man should identify himself.

DR. DIXON, the Medical Officer of Health for Bermondsey, in his annual report to the vestry, just published, gives the number of uncertified deaths during the year as sixty-six, or 3.8 per cent. of the total deaths. Forty were males and twenty-six females; thirty-eight were children under one year of age, and twelve were between one and five years. He adds: "From the use of such purely professional terms as *spina bifida*, *pyæmia*, *hydrocephalus*, and *tabes mesenterica*, it is evident that the information given to the registrars was supplied by medical students, unqualified assistants, or practitioners who were not on the medical register of persons duly qualified to practise."

## Annotations.

"*Ne quid nimis.*"

### THE HEALTH OF THE PRIMATE.

THE grave apprehensions of the friends of the Archbishop have not been hitherto realised as to the result. The Primate continues to live, and to show a vitality which is apparently natural to his family. We reported on the 2nd instant a state of things which indicated the most imminent danger to his life, but the comatose state which then appeared as about to bring an end to existence has departed, and left the mind of the Archbishop perfectly unaffected. The impervious left lung has become pervious again, without the intervention of crepitation or bronchophony, whilst the pneumonia in the right has developed moderate consolidation. The insufficiency of the cardiac valves, which was very manifest before his Grace's feverish state began, has not been evident since he has kept the recumbent position, but the pulse continues frequent, varying from 90 to 100 daily; whilst the Archbishop's normal pulse was usually 72; it is of fair power, though a beat is lost occasionally. There are no cardiac murmurs now. The respiration has become gradually slower, falling from 40 to 30 per minute. The cerebral character of the respiration has departed. This was very manifest whilst the comatose stage threatened. The thrombi in the legs have nearly disappeared. The skin continues dry, as well as the mucous membrane of the mouth and throat. A few aphthous spots appeared on the tongue and the palate in the early part of the week, causing some uneasiness in swallowing; but these have departed, as well as the accompanying nausea. There is considerable emaciation, but food of an unstimulating character is taken in abundance and without any distaste. The Archbishop sleeps uneasily, but has not been troubled with much pain of any decided kind. The neuralgia in the shoulder, right arm, and back of the neck has left him.

### CHOLERA AND QUARANTINE.

THE rumours of cholera and of the adoption of quarantine measures in different parts of the world remind us of a danger to which Europe is annually subjected at this season of the year, and also of a preventive measure which finds many staunch supporters in the East, but which in this country is every year coming to be regarded with diminishing assurance in so far as its effect upon public health is concerned. For ourselves, the most disquieting rumour has had reference to the presence of cholera in the Red Sea, and to the imposition of such quarantine measures upon vessels entering the Suez Canal as would seriously have hindered our operations in Egypt. The rumour, so far as the cholera was concerned, has turned out, to say the least, to have been greatly exaggerated, and it is indeed doubtful whether true Asiatic cholera was in question; so, also, the prompt intimations of our Government have prevented the adoption of measures which, whilst probably useless in themselves, would have caused a serious hindrance both to England and to other European countries. It must not, however, be forgotten that, as pointed out by Mr. Netten Radcliffe, by the opening of the Suez Canal the Red Sea has become the most ready route for cholera to enter Europe, and it was to have been hoped that some international arrangements might have been made for the proper inspection and regulation of infected and suspected vessels, which, whilst avoiding the needless restrictions attaching to the more antiquated of the so-called quarantine measures, would have provided for the security of Europe from infection by that route. There are, however, now many difficulties to be overcome before any international agreement can be expected with regard to

this question, and, in the meantime, we may in this country fully trust to the sanitary organisation of our ports, if the authorities having control over them rigidly carry out their inspectorial duties as regards shipping, and also provide themselves with means for the isolation of the infectious sick.

#### MECHANICAL STIMULATION OF THE BRAIN.

VARIOUS opinions have been expressed regarding the degree to which the cortex cerebri is excitable by mechanical agencies. Few experimenters have found the mechanical excitability to be well marked. The most noteworthy results thus obtained are those of M. Couty, who described movements as produced by such stimulation of the motor region, the effect closely resembling that following electrical stimulation. He stated, also, that these movements could be increased by causing inflammation in the cortex, either by exposing it to the air for a certain time, or by the action of various irritant substances. The nervous tissue becomes a little more consistent in consequence of the inflammation, and is less easily reduced to a soft pulp by mechanical disturbance. The effects obtained by M. Couty were of two orders: movements first on the opposite side of the body; and, secondly, on the same side as the hemisphere irritated, and in certain cases movements more or less general were produced. The first of these alone are comparable to the results of electrical stimulation of the motor zone, the others must be regarded as of the nature of reflex actions—i. e., of sensori-motor nature. M. Vulpian has recently made a large number of experiments to ascertain the degree and character of the mechanical excitability of the grey cortex of the brain. In mammals, dog, cat, and rabbit, in the normal condition, he could never produce in this way the slightest movement either in the limbs of the opposite side, or in those of the same side. The mechanical stimulation was produced by rubbing the surface of the cortex with a small sponge, or a fragment of amadou, or with the points of dissection-forceps. Thus, in the dog and cat, after having carefully ascertained the points in which electrical stimulation produced movement of the face, or of the fore limb, or of the hind limb, varied mechanical stimulation was applied to the same points, but no movement could in any case be perceived. If therefore movements resulted from such stimulation in the experiments of Couty, the effect must have been purely accidental, or the consequence of some experimental error. The results were also negative when Vulpian repeated the experiments, after having produced inflammation of the surface of the sigmoid gyrus by tincture of cantharides, by essence of mustard, or by nicotine. The stimulation of the inflamed surface by various mechanical agents did not cause the slightest movement in any part of the body. Nevertheless, in Vulpian's experiments, certain effects were observed analogous to those which Couty regards as reflex, and which are produced by the mechanical excitation, not of the motor functions of the cortex, but of the sensory regions. When the sigmoid gyrus of the dog is galvanised or faradised, a certain amount of pain is produced even when the electrodes are placed a long way from the shreds of the dura mater, which are extremely sensitive. The points in this region which seem to be the most sensitive are those in which stimulation causes movement of the fore or hind limb on the opposite side, although these are far less sensitive than is the dura mater. But mechanical stimulation of these regions never, in Vulpian's experiments, caused indications of pain. Nevertheless, similar excitation of the deeper layers of the cortex, or in the subcortical portion of the white substance, usually caused unequivocal signs of suffering. When metallic wires are passed into the motor points of the sigmoid gyrus, and a faradaic current of moderate intensity is passed through them, the movements caused in the limbs on the opposite

side become stronger the deeper the wires are plunged into the cerebral substance, provided they penetrate to the white substance. These movements are absolutely the same as those which are produced by faradisation of the surface of the convolution, and differ only in their greater extent and greater energy. In the same way, the pain becomes more intense when the wires reach the white substance. Thus the sensibility of the cerebrum itself is incontestably low. It is, however, augmented by repetition of the stimulus and thus it is possible that pathological irritation may cause an exalted sensibility, which is evidenced by pain. It is only in the white substance beneath the sigmoid gyrus that mechanical stimuli elicit any evidence of sensibility. Elsewhere the white substance of the cerebral lobes seems to be absolutely insensible, although on this point M. Vulpian's experiments are not sufficiently numerous to enable him to speak with perfect confidence.

#### METROPOLITAN LUNACY.

NOTWITHSTANDING the provision of three large Middlesex County Asylums at Hanwell, Colney Hatch, and Banstead (to say nothing of the Surrey and Kent County Asylums), and of three Metropolitan Asylums for Imbeciles at Lewisham, Caterham, and Darenth, there is constant and increasing complaint among the Guardians of the Metropolitan Unions of the difficulties in which they are placed through want of accommodation for lunatics, now improperly retained in the workhouses. It appears that the subject has been under serious discussion by at least three Boards of Guardians—namely, those of Poplar, Mile-end Old Town, and Wandsworth. The present institution-provision for metropolitan lunatics and imbeciles is evidently insufficient, and bearing in mind the serious evils attending the retention of lunatics (especially new cases) in workhouses, this subject seems to call for full inquiry. It is not disputed that the county asylums are overcrowded with incurable cases, and this renders it the more important that additional accommodation should be at once provided for such cases in order to render available space for the prompt reception and treatment of new cases, a large proportion of which may be deemed curable. With regard to the accommodation provided by the Metropolitan Asylums Board, it may be stated that at the present time about 4000 patients are accommodated in the two asylums at Leavesden and Caterham, whereas not more than about 400 are yet in residence at the third asylum at Darenth. It seems a matter for regret that the Metropolitan Asylums Board do not see their way to relieve the pressure for lunacy accommodation in the metropolis by promptly rendering additional space available at Darenth.

#### SANITATION AT GREENOCK.

HITHERTO we have had little enlightenment in sanitary matters at Greenock, as throughout its existence the town has been chiefly noted for its neglect of all sanitary laws, for its high death-rate, and its enormous rainfall. But better days seem to have dawned of late, and few more complete expositions of the advantages of efficient sanitary legislation have been given than that offered last week by Mr. George Mackay, the Greenock sanitary inspector, in a speech to the Sanitary Association of Scotland. In 1876 the local authority of Greenock obtained special Parliamentary powers, and it has used these to such purpose that the contrast between the health record of the past and present is most instructive, and ought to be so to those armed with, or requiring, such authority in other towns where such proclivities as were found in Greenock may still abound. Taking an average of ten years, there were many densely populated places with a mortality

from 40 to 67 per 1000 of the population; the general rate was higher than that of any other large town in Scotland, the mean during the twenty-one years prior to 1876 being 31·24 per 1000. During the five years immediately succeeding the institution of an improved sanitary system the mortality sank to the less frightful rate of 24 per 1000, while in 1881 it only reached 22·14, being the lowest rate hitherto recorded in this long-suffering town. It was in infectious diseases that the greatest decrease of deaths had taken place, the quinquennial period after 1876 showing no less a reduction than 1123 as compared with the period immediately preceding that date. Mr. Mackay may well give credit to the present administrators of health matters in Greenock for their enlightened policy. It may not be amiss to point to the further fact that this is one of the few towns where the burthen of reporting infectious diseases is thrown upon the householder; and though Dr. Wallace is not satisfied, we can well see that much may be said in favour of a system which gives such excellent results, while leaving undisturbed the feeling of mutual confidence so necessary between practitioner and patient.

#### TESTIS IN PERINEO.

DR. S. BAUDRY has recently met with a case of the rare malformation in which the testicle, instead of descending into the scrotum, passes down into the perineum. The subject of the deformity was a new-born child, in other particulars well developed and well nourished. The right testicle was found two centimetres in front of the anus, and the same distance outside the ano-scrotal raphe; it presented normal characters, being slightly smaller than the one on the opposite side; the vas deferens was readily traceable up to the external abdominal ring. This testicle was covered by normal skin. The right half of the scrotum appeared to be absent; the raphe was seen on the right side, and from it the skin continued without fold or line of demarcation to the thigh. No sign of any dartos could be found to the right of the raphe, for while cold caused distinct contraction on the left side none was observable on the right. The displaced testicle was not movable. In this case differs from others that have been recorded, for in the accounts of such cases it is usually stated that the testicle was readily moved up into the groin, and in some it always assumed this position in sitting and walking, and all the treatment required has been to fit on some form of suspensory bandage to keep it up in the groin. Hunter was the first to draw attention to this rare deformity of the testicle, and the difficulty he experienced in accounting for it has in the opinion of pathologists not yet been satisfactorily overcome. Mr. Curling, who reports more cases than any other observer, attributes it to the action of a gubernaculum testis, of which the middle slip is attached to the perineum instead of to the bottom of the scrotum; and there is certainly much to be said for this view, the strongest piece of evidence in its favour being the fact that in a case in which Mr. Curling attempted to replace the organ he found a very firm band attaching its lower end to the superficial structures of the perineum. On the other hand, some authorities doubt whether the gubernaculum testis is the cause of the descent of the testis, and whether therefore its faulty attachment can lead to a misplaced testicle. In only a minority of the recorded cases has the corresponding side of the scrotum been absent, so that we cannot attribute the deformity to want of development of the normal receiving pouch. More frequently the scrotum is shrunken, and in two cases Mr. Curling and Mr. James Adams attempted to replace the testicle in its proper scrotal pouch. Mr. Hutcheson has seen a boy with both testicles in the perineum. Vidal observed it in two brothers. It is well known that testicles retained in the abdomen usually fail

to secrete spermatozoa. Such appears not to be the case when the organ reaches the perineum; in one case Ledwich dissected a specimen, and although the organ was small and soft, its ducts were found to contain spermatozoa. The most important question is that of the proper treatment. There is no evidence to show that the testicle is in these cases specially prone to become the seat of malignant disease, nor associated with hernial protrusion. When it is movable a retentive apparatus, which keeps it out of the way of injurious pressure during sitting, riding, and walking, answers all the indications. In such a case as Dr. Baudry's, where the organ is fixed, it would be wise to wait to see whether it may not become mobile, but should this not occur it would undoubtedly require excision, as it would be constantly exposed to injury in sitting or riding. A case is recorded in which a perineal testicle became affected with gonorrhœal inflammation, and was almost incised in error for an abscess. Zeiss mentions the curious coincidence of this deformity in a boy suffering from stone in the bladder, and the misplaced testicle—the left—was only discovered when he was about to commence the operation of lithotomy. Its position was such that he was forced to cut on the right side.

#### THE NECESSITY FOR HOLIDAYS.

IF it were strictly true, as Dr. Fothergill assumes in a paper in the current number of that always entertaining and useful publication, *Good Words*, that "some little time ago, not more than a generation, holidays were associated with school children, and rarely did anyone of adult years talk of a holiday," that would go far to prove that the "necessity for holidays" was a demand created by supply. Such, however, is not quite the fact. It is undoubtedly true that holidays are more common than they used to be, and that they are now enjoyed by classes of the people to whom they were until recently unparticipated luxuries; but for all time it has been the practice of brain-workers to rest from their labours for a short time periodically. Those who did not do this, except in rare instances of particularly wisely ordered work or of extraordinary vigour, were compelled by an oft-recurring threat of breakdown to take therest they would otherwise have refused. In short, holidays are a necessity, growing out of the physiological need for periods of store-replenishing, when the reserves of strength can be made up. It is impossible to lay too great stress on the fact that the economising of the buoyancy and vigour of life very much depends on the integrity of those reserves of mental and nervous force which it is the main purpose of the holiday to replenish. Mere "rest" will not accomplish this result. Every part of the organism, the brain and nervous system included, feeds as it works. There must be exercise, or there will not be appetite; and without appetite an abundant supply of food is of little avail.

#### BLUE MARKS AND PEDICULI.

SOME years ago the fact that blue spots or dusky spots are often observed in association with pediculi pubis was pointed out by M. Mourou, a French naval surgeon. Subsequently M. Duguet furnished a demonstration of the relation between the two by producing blue spots by means of inserting beneath the epidermis a small quantity of a sort of paste made of bruised pediculi. Hence it is clear that the pediculi pubis contain some substance having colouring properties. Farther observations by M. Mallet, a pupil of Duguet, make it probable that this substance is contained in the salivary glands. By means of fine forceps the head of a pediculus was torn off and inserted beneath the epidermis of the forearm, and near it the rest of the louse was similarly interred. Next day a blue

mark was distinct around the body of the insect, but not around the head. In another experiment a small mass came away from the body of the insect with the head, and in this case the dusky spot developed around the head and not around the body. Further experiments showed that the colouring agent was situated in the body opposite the anterior pair of legs, and at this level it is known that there are two pairs of salivary glands. M. Duguet has pointed out some curious facts regarding the resistance of some persons to the action of the salivary juice and the influence of season on the colouring power of the insect. The blue spots are far more abundant in February, March, and April than in other months.

#### THE PARKES MUSEUM.

THE Council of the Parkes Museum have just acquired new premises in Margaret-street, Cavendish-square, to which the museum is to be removed from University College as soon as the alterations and additions which are now being made under the direction of Mr. Mark H. Judge, A.R.I.B.A., are completed. The new museum will consist of a central hall, suitable for meetings and lectures, a library and corridors, all lighted from the top, and well suited for exhibition purposes. The meetings and lectures on sanitary and other matters connected with the health of the people, which were only occasional while the museum was at University College, will form a permanent feature of the institution when it is reopened in Margaret-street. Captain Douglas Galton, C.B., F.R.S., presided at the last meeting of the Council, when a letter was read from Mr. Thomas Twining of Twickenham, in which he said: "Much as I regret that University College should lose the advantage of possessing a hygienic collection within its walls, I cannot but rejoice at the prospect now afforded us of developing the Parkes Museum in a central position, with all those educational devices which may unite the benefit of the people at large with that of the medical, architectural, and engineering student. The outset will necessarily involve considerable expenditure, but with such results in view, I should think that many liberally minded friends of sanitary progress might be induced to join in meeting this extra expense." Mr. Twining concluded his letter by offering to contribute a special donation of £100 towards these expenses. In accepting the generous offer of Mr. Twining, the Council passed a vote of thanks to him for the timely help thus rendered to them. It is expected that the museum will be reopened before Christmas. In the meantime communications may be addressed to the Secretary and Curator, Mr. Mark H. Judge, at 8, Park-place Villas, Paddington, W.

#### ISOLATION PROVISION FOR NOTTINGHAM.

DR. SEATON, medical officer of health for Nottingham, strongly urges the provision of a permanent hospital for the isolation of infectious diseases. The present hospital buildings, which are situated in the centre of the borough, were hurriedly erected in the face of an epidemic of small-pox some ten years ago, and they have recently served for the isolation of the same disease. But they are reported as unfit for the isolation of more than one infectious fever at a time; they are not suited to the reception of scarlet fever cases; and, in short, they do not constitute the sort of hospital provision which should be provided for the protection of public health in such a town as Nottingham. Public opinion would now appear to favour Dr. Seaton's contention; and it is to be hoped that a corporation which has already shown itself capable of meeting many public and educational wants in a way that leaves but little to be desired, will no longer defer making this much wanted addition to the means it already possesses of coping efficiently with infectious disease.

#### THE DISTRIBUTION OF THE HOSPITAL SUNDAY FUND.

OUR contemporary, the *Morning Post*, has opened its columns to an expression of complaint on the part of those who are not satisfied with the distribution of the Hospital Sunday Fund. "A Governor of Hospitals" supplies the following table of awards to the principal hospitals:—

Hospital.	No. of Beds.	Sum awarded.	Per Bed.
King's College	200	£1575 0 0	£7 17 6
St. Mary's.....	190	1012 10 0	5 6 6
University ...	200	1012 10 0	5 1 3
Middlesex ...	310	1462 10 0	4 14 4
St. George's...	351	1575 0 0	4 9 8
Charing-cross	180	675 0 0	3 15 0
Royal Free ...	160	562 0 0	3 15 0
Westminster...	215	787 10 0	3 13 3
London .....	800	2812 10 0	3 10 3

The writer very properly says that the Distribution Committee sits as a sort of jury on hospitals, and by its awards expresses a kind of judgment on the administration of each particular hospital. At the last meeting of the Council the inequality of the awards was alluded to in a letter by Sir Rutherford Alcock, and it was understood that the principle of distribution should be again fully discussed. We ourselves have complained occasionally that the awards were not very intelligible. It is to be admitted, however, that they have excited exceedingly little complaint among the great Hospitals themselves. A "Governor of Hospitals" complains that the London Hospital in the recent distribution got less than half what King's College received. It is nevertheless true that Sir Edmund Currie, one of the most devoted friends of the London Hospital, entirely sanctioned the last distribution, and made no complaint on behalf of his favourite institution. The distribution is made on an arithmetical basis, exclusive of legacies over £100, and the Committee are expected to consider the *merits and needs* of each particular institution: a consideration which largely takes the shape of a comparison between the expenditure on the maintenance of patients and that on expenses of management. The Distribution Committee have very ample details of information, and are generally able to give some account of their awards. But they are not likely to be indifferent to any well-grounded complaints of the working of what they are fond of calling "the arithmetical basis."

#### THE URINE IN INFECTIOUS DISEASES.

A SERIES of researches, chiefly by Selmy, Brouardel, Boutmy, and Gauthier, have shown that peculiar alkaloids, to which the term "ptomaines" has been given, develop in dead animal tissues which are in process of putrefaction. They present similar chemical reactions to the alkaloids which are found in poisonous fungi. Bouchard, according to the *Revue Médicale*, has suggested that, since the ptomaines only appear in tissues which are charged with microscopic fungi, it is permissible to suppose that the cadaveric alkaloids are merely the products of the "disassimilation" of vegetable organisms. Further, if bacteria living in the dead animal tissues produce bacteria, it is possible that the same bacteria, growing in a living organism, may produce substances analogous to ptomaines. Bacteria seem to appear in the living body in all infectious diseases. Hence M. Bouchard has endeavoured to ascertain whether, during the course of infectious diseases in the human subject, any trace of these alkaloids can be found in the urine. His observations were made on cases of typhoid fever, "infectious pneumonia," and "infectious pleurisy," whatever the latter disease may be. All were dieted and no medicines containing alkaloids were given to them; and the urine was carefully preserved from putrefaction. An analysis showed

that they contained alkaloids having all the characters of ptomaines. A series of normal urines examined, and specimens from patients suffering from pulmonary emphysema, valvular disease of the heart, presented no trace of alkaloids. The conclusion, however, is not beyond question, since M. Pouchet has affirmed that the presence of alkaloids may be constantly demonstrated in normal urine.

### THE SANITARY CONDITION OF AUSTRIA.

THE Austrian Commission of Statistics, in its annual report upon the sanitary condition of the country, states that the number of hospitals is 505, with 28,466 beds, and that in the course of last year 237,772 patients were received in them, this being in the proportion of one to eighty-four of the total population. The number of lunatic asylums is 26, with 5934 beds, and the inmates last year numbered 8867; showing an increase of 7 per cent. since 1876, the proportion of men to women being as 54 to 46. There are eighteen lying-in hospitals with 1517 beds, and they received last year 16,649 mothers and 14,861 infants. The births in these hospitals numbered 15,241, of which 12 per cent. were twins and one-half per cent. triplets. The proportion of foundlings in Austria is one in 735 inhabitants, the greatest number being in Vienna and Lower Austria generally. There are in Austria fifteen schools for the deaf and dumb, with 1243 inmates, and eight asylums for blind children. It is estimated that there are outside these different hospitals 16,123 insane persons, 13,462 idiots, 20,843 deaf and dumb, and 11,730 blind. The number of thermal establishments is 220, visited last year by 150,496 persons, the Tyrol having 84 of these establishments, Styria 24, and Bohemia and Galicia 21 each. There are in Austria 4603 physicians, 2971 surgeons, 400 veterinarians, and 15,569 midwives and professional nurses, the number of medical men in Vienna being at the rate of one to every 582 inhabitants, while in some of the northern provinces there is not more than one to 10,000. The total number of deaths was 613,661, or 33 in the thousand; and of this total 13,313 died of small-pox, 4354 of measles, 15,819 of scarlatina, 15,257 of typhus, 7791 of dysentery, 348 of European cholera, 56,973 of croup and diphtheria, 56,551 of bronchitis, and 85,457 of consumption, while 10,390 came to a violent end, including 3480 suicides.

### THE TREATMENT OF TYPHOID.

AT the present time the treatment of typhoid fever is an opportune subject to engage the attention of the medical societies of Paris since the French metropolis is threatened with an epidemic of most serious proportions. The subject was brought before a recent meeting of the Académie de Médecine by M. Vulpian, who is applying his experimental skill to the service of practical medicine, and has been recently endeavouring to determine the value of the antizymotic treatment of the disease. The question is one of extreme importance, for it must be admitted that hitherto the advance of bacterial pathology has not resulted in that increase in our power over developed disease which might reasonably have been anticipated from so considerable an addition to our knowledge of the nature of morbid processes. There is strong reason to regard typhoid fever as of parasitic origin, and from this naturally follows an expectation that good may be done by germicide remedies which may reach the intestine without losing their influence. Nevertheless this method of treating typhoid fever has hitherto found little favour at the hands of practical physicians. Proceeding upon these lines, M. Vulpian has tried in turn iodoform, which caused only disgust; salicylate of bismuth, which, although of a certain efficacy, seemed to favour the occurrence of certain complications, such as dyspnoea and nasal

and intestinal hæmorrhages; boracic acid, which turned out as useless as iodoform; and, lastly, salicylic acid, to which M. Vulpian wished to draw the special attention of the Academy. It may be remembered that this was largely tried, especially in Germany, several years ago, but generally relinquished as being either useless or positively injurious. M. Vulpian found that when it was given in small doses, as one, two, or three grammes in the twenty-four hours, the results were almost *nil*, but if a quarter of a gramme was given every half hour, so that the patient took in the day about six or seven grammes of the pure acid, he believed that there followed an amelioration in the course of the disease both marked and lasting. Some patients presented the accidents of salicylism—delirium, which quickly subsided when the drug was discontinued, or a little albuminuria, but these were exceptional. In most cases these doses were well borne, and the beneficial influence of the drug was shown in improvement of the general condition and of the mental state, and especially in a fall of temperature, which had a permanence not observed with other antipyretic remedies, such as carbolic acid. These results are in striking contrast to those obtained by other physicians who have tried salicylic acid in typhoid. M. Germain See, for instance, declared that he had never observed a true and lasting defervescence to be obtained by its use, but only a transient fall of temperature of a few tenths of a degree. It remains to be seen whether the results obtained by M. Vulpian are not due to the series of cases thus treated having been of a mild type. The difference in epidemic severity is a fertile source of fallacy regarding the treatment of typhoid. Experimental physiologists are often apt to draw hasty and untrustworthy conclusions on points in practical medicine.

### DEATH OF A MEDICAL MAN FROM CHLORAL.

THE *Hertfordshire Mercury* gives the report of the inquest on the death of Dr. G. A. Towers, in his eightieth year, of Sele Cottage, North-road, Hertford, the son of Mr. John Towers, an eminent horticultural chemist, and a direct lineal descendant of Dr. Samuel Towers, a distinguished physician and chemist of the seventeenth century. Dr. Towers, after his apprenticeship, tried business on the Stock Exchange, but not being successful, reverted to the study of medicine, and finally graduated at St. Andrews. He was a man of various talent, given to music, painting, photography, horticulture, &c. He was the first resident medical officer of the County Infirmary, and the friend of Drs. Davies, Furnivall, and other physicians of Hertford. It is lamentable to record that Dr. Towers came by his death through an overdose of chloral, a drug to which he was much addicted. Mr. Odell said at the inquest that the deceased had told him that he had taken as many as 180 grains. It is bad enough for any person to drift into such a habit, but in a medical man it is much worse. He must know the tendency of it to be only evil, and his example is likely to be so much the more injurious.

### ALONE.

A DISTRESSING case of suicide committed by a boy ten years of age, while in his bedroom, to which he had been sent as a punishment, draws attention once again to a practice on which we have often commented adversely—namely, that of leaving children, young persons, and the weakly or troubled in mind, *alone*. The solitary state is abhorrent to the nature and mind of man. Whether the brain be immature in its development or morbid in its state, it is wrong in a scientific sense—that is, opposed to the laws and teachings of physiological science—to leave it alone. The possibility—we will even concede the probability—of a subsidence of excitement is not a sufficient set-off against

the dangers of a self-destructive intellectual activity. The mind always works to its own injury when it works alone. Reflection, introspection, and self-examination are essentially abnormal processes. The proper action of mind is on the outer world, or on such conceptions of fact and object as may be readily corrected by present observation or experience. Abstract processes of thought are never safe for the young or the weakly and troubled in mind. Healthy activity, so far as these two conditions of mind are concerned, is directly relative. It is not good for man to be alone in any sense. We would therefore again protest against the recourse to solitary confinement as a punishment for children, and against "seclusion" in any form for the unsound of mind. The two methods of treatment stand on the same footing, and they are both equally bad.

#### THE INOCULATION OF SYPHILIS.

A FEW weeks ago we directed the attention of our readers to the interesting observations which have been made in Germany, of the frequent association of bacteria, fairly definite in characters, with the tissue changes produced by syphilis, and we pointed out that the relation between the organisms and the disease cannot be more than probable until culture experiments and inoculations shall have given some positive results. The subject has been further investigated by a French syphilographer, M. Martineau, but it may be doubted whether it has been advanced by his researches. His search for organisms in the blood, chancrous induration, and cutaneous manifestations of the disease has been fruitless, but another method of procedure has led to results which he regards as more definite. A recently excised chancre was placed in a closed vessel which had been previously heated to a red heat. A concentrated "bouillon" was prepared and boiled for about two hours. It was then placed in a flask with a long neck, the temperature was lowered to 30° C., the chancre was introduced, and the neck of the flask was sealed at the lamp. The liquid was found, next day, to contain numerous bacteria of a special form, and a day later some of it was injected into the peritoneal cavity of a pig five months old. In a month seven or eight prominent papules appeared on the abdomen, followed by others. A few days afterwards conjunctivitis appeared in one eye, and a tumour on the penis. For the sake of comparison another pig was inoculated with pus from a syphilitic chancre, with the result of causing an eruption exactly similar to the first. Some bacteria were found in the blood of the second animal, and were injected into a third pig, a goat, and a monkey, but without result. The blood of these animals presented no bacteria. M. Martineau thinks that the cutaneous affection observed on the first two pigs presented the characters of a syphilitic eruption, and he concludes that syphilis is transmissible from man to the pig, but not from it to other animals, nor to other animals from man—a conclusion for which the facts of his experiments certainly give him only the most slender basis. His operations are to be reported on by a committee composed of MM. Bouley, Pasteur, Fournier, and Lancreaux.

#### DEAFNESS IN SCHOOLS.

THIS is a matter of considerable moment. There seems to be some ground for supposing that deafness is more common among children than the cases recognised would imply. At Washington, in the United States, an inquiry has been instituted with the result of discovering a notable proportion of instances. It would be well if tests were applied in the schools of this country—to ascertain the facts, and, if these should be adverse, to try to discover the reason why, and the mode of preventing what is one of the most troublesome and depressing of common calamities.

#### THE HABITUAL DRUNKARDS ACT.

THE office of Inspector of Retreats under the Habitual Drunkards Act cannot be a very lively or satisfactory one, owing to the want of anything particular to inspect. In the inspector's second report, just issued as a Parliamentary paper, only two establishments were reported on: the original one, Hall Court, Cannock, Staffordshire, and Tower House, Westgate-on-Sea. The first, with accommodation for ten male patients, was closed during the year in consequence of a want of harmony between the licensee and some of his patients; it has been opened since. At the Tower House, Westgate-on-Sea, six patients were admitted and two discharged, leaving four on the books on December 31st. The inspector fears that public-houses in the vicinity of the Retreats will give trouble, especially where there are not extensive grounds for recreation or a sufficiently large staff for purposes of discipline. He reports that some patients have done well up to the day of their leaving the retreats, but that in some cases they have immediately on their discharge given way to their prevailing vice; others have obtained drink during their very residence. Was there ever such an impotent piece of legislation as this? The result may satisfy those who prefer freedom to sobriety; but it can satisfy no one else to know that the habitual drunkard is still his own master, or rather the uncontrolled slave of his own vice.

#### THE CHAIR OF SURGERY AT ABERDEEN.

DR. PIRRIE has for so long a time been such a prominent member of the professional staff of the University of Aberdeen, that his retirement cannot but be regarded as an event of considerable importance. While some will be found to regret that he did not continue labouring in the field in which he had been so successful, we fancy that many more will be glad that he has not put off the day of retirement until the infirmities of age by incapacitating him for his duties have left him no choice. Dr. Ogston, Dr. Forbes Moir, Dr. Ogilvie Will, and Dr. R. J. Garden are candidates for the chair. But it has attractions for others besides "local" men, and we learn that Mr. Canthie, of Charing-cross Hospital, a very distinguished alumnus of Aberdeen University, who is very favourably known in London for his marked ability as a teacher, is also in the field, and will no doubt prove a formidable rival.

#### PRESCRIBING DRUGGISTS.

THE recent address of Dr. Attfield has given rise to various suggestions, not all original, as to the line which should distinguish those who prescribe medicine from those who compound and dispense it. We shall not range ourselves on the side of the unpractical, and say that this line should be absolute. Medical men will not quarrel with it if it be not carried too far. The public must be its own judge in the matter; but the more the public knows and becomes intelligent about disease, the more it will see the real economy of having the best opinion upon it that can be got. The prescribing work of chemists is the foil to set off the more cultivated work of the medical practitioner. We speak in no bombastic spirit. Disease is often puzzling enough to medical practitioners. It must be still more to those who have had no medical education. Of all suggestions on this subject that is the most pernicious which would give chemists a smattering of medical knowledge. Let us have no revival of the inferior half-fledged doctor. Let us have one thing or another—a chemist or a doctor. There is plenty of imperfect medical education already. We do not want any more superficialness or sham. The public would be injured most seriously by the success of any such proposals. If knowledge of disease is thought to come to chemists by reading the pre-

scriptions of others, let it be so; but let us not give any public sanction to the notion that a "smattering of medical information" imparted to a chemist will make him a doctor.

#### RAILWAY WHISTLES AND WHISTLING.

WE quite agree that there is far too much whistling on railways; but it is not true, as stated in a paper read by Mr. Price Edwards before the British Association, that "a low note would be equally efficacious for railway purposes as a high one," because "given the same initial intensity in the production of two sounds—one of low, the other of high pitch—there would be little difference between their penetrating powers at long distances, and none at all at such distances as sounds are required to be heard for the purposes of signalling." There is some begging of the acoustic question in the way the proposition is stated; but setting that aside, it is notorious, and capable of demonstration, that a flat note does not penetrate so well as a full one of the same pitch, and all sounds have a tendency to fall flat as well as to be less distinctly heard as they traverse space. In other words, the trajectory of the sound-wave falls flatter as it is prolonged. It follows that a low sound which has naturally a low trajectory will become flat sooner than a high one. If whistles are to be heard, and it is essential they should be, at great distances, they must be high-pitched. Meanwhile public health and happiness demand that there should be as little use of the railway whistle as possible.

#### DEATH FROM CHLOROFORM.

MR. COLLIER, Deputy Coroner for East Middlesex, held an inquest on the 7th inst. on the body of Mr. Francis Mellish de Putron, aged fifty-eight, a builder, of 3, Lower Gray-street, Silvertown, who had died under the influence of chloroform. It was stated that the deceased had been suffering from cancer of the tongue, and had attended the London Hospital for the purpose of undergoing an operation. Mr. Basil Wood Walker, house-surgeon at the hospital, said that the deceased was admitted on the 16th of August, suffering from cancer of the tongue, and it was decided that, with the consent of the deceased, an operation should be performed. On Sept. 4th chloroform was administered to him by witness, and it was not considered necessary to examine his heart. While under the influence of the chloroform he struggled, which was usual with persons when it was administered. The pulse then stopped, the deceased became livid in the face, and he commenced gasping. Restoration was tried, but without effect, and the operation was not commenced. Death ensued between five and ten minutes from the time the chloroform was first administered. The cause of death was failure of the heart's action, and the jury returned a verdict to that effect.

#### THE THAMES AS A GUTTER.

FILTH is thrown into the gutters of streets running through low-class neighbourhoods by persons having no exalted sense of the duties of good citizenship, and the agents of the Corporation of London and the Commissioners of Sewers discharge the contents of street gullies or gutters into the Thames. That highly respectable, if not very poetical, or even classic river is therefore little better than a gutter for the metropolis, so far as the uses to which it is put by the authorities above mentioned are concerned. It is not much good to protest, because the offenders are corporate bodies, and such organisations work their will at all costs and against all objectors. Nevertheless, we echo the suggestion that the Corporation and Commissioners of Sewers of London should be respectively summoned before the Lord Mayor, and, if possible, fined ten shillings and costs, with the view of bringing them, if possible, to their senses.

#### DR. PUSEY.

DR. PUSEY's condition is less satisfactory. His age is eighty-three, and gradual and increasing debility is the only feature in the case. His mind is perfectly clear.

#### VACCINAL MICROCOCCI.

M. STRAUS presented to a recent meeting of the Société de Biologie a series of microscopical preparations of the vaccinal pustule from the calf, at different stages of its progress, in which the presence of the special micrococcus could readily be observed. The method of preparation adopted was to place the excised fragments of skin in absolute alcohol, to cut sections and stain them by the method of Weigert, which consists of tinting with methylamine violet, and then discolouring them until only the nuclei, the bacteria, and micrococci remained visible. Under a strong magnifying power the latter were visible as extremely minute points, tinted blue, about a thousandth part of a millimetre in diameter, and grouped in colonies. They were seen in the borders of the inoculation wound, and in the Malpighian layer, and subsequently could be traced passing into the subjacent cutis, especially in the lymphatic spaces. The multiplication and extension of the organism seemed to coincide closely with the development of the pustule.

#### LONGEVITY OF AMERICAN DOCTORS.

AT the annual meeting of the Massachusetts Medical Society, held in Boston last June, the secretary read the names of Fellows deceased during the preceding year. They numbered 33. Of those, 13 had attained the age of sixty-five and upwards; 9 were seventy and above; 3 were respectively eighty, eighty-one, and eighty-eight; while the Nestor, Dr. Ebenezer Smith Phillips, admitted a Fellow in 1837, died the 28th of last May, aged ninety.

#### COMPULSORY VACCINATION IN ZULU.

OUR correspondent quotes the *Cape Mercury* as stating that the Zulu King Panda, twenty years ago, had himself and his son Cetewayo and all his subjects vaccinated by a medical man whom he sent for from Natal. We cannot despair of a royal family, even of savages, that can act with an enlightenment that would put to shame some of the members of our own House of Commons.

A CONSIDERABLE addition to the present water-supply of Hawick is all but completed. Some time ago a new system of sewerage was adopted, which necessitated the use of a quantity of water so great that the old supply from the river Allan was insufficient, while the rapidly increasing population of the town demands that prompt measures should be taken. A tributary of the Allan has now been requisitioned, and upon it, at an altitude of nearly 700 feet, a twenty-acre reservoir has been formed. The town will now have a certain daily supply of sixty gallons per head to the present population, so that another extension is not likely soon to be required. The recent operations, without ground charge, will cost over £14,000.

WE observe that Charing-cross Hospital had the honour, on the occasion of the recent examination for commissions in the Indian Medical Service, of turning out the first and second men. Mr. Albert Leahy, F.R.C.S. Eng., at present assistant-surgeon to the Royal Westminster Ophthalmic Hospital, and Mr. W. W. Webb, M.B., C.M., may be congratulated on gaining for themselves and their hospital the first two places out of no fewer than forty-two candidates.

A CAPACIOUS new gallery, erected from the drawings of the College architect, Mr. Alfred Waterhouse, has just been added to the Anatomical Museum of the Medical School at Owens College. The new gallery, in uniformity with the two already constructed, goes entirely round the building, and arrangements will shortly be made for filling it with classified specimens. The building has also been covered with a new roof of skylights, by which means a considerable advantage has been gained by securing additional light throughout the Museum.

THE metropolitan Medical Colleges and Schools will all open on Monday, the 2nd of October. At King's College there will be an address by the Right Hon. W. H. Smith, M.P.; at University College an address by Dr. Marcus Beck; at the Middlesex Hospital Medical School by Dr. Robert W. Lyell; at St. Mary's by Dr. Chambers; at St. Thomas's by Dr. Sharkey; at Westminster by Dr. de Havilland Hall; and at St. George's by Dr. Herbert Watney.

THE Sanitary Authority of Wednesbury has deemed it necessary to open eight of the hospital tents to receive small-pox patients, who are to be attended by a special surgeon from London. During the past fortnight there have been sixty fresh cases and seven deaths. The utmost is being done to stamp out the disease by means of isolation and disinfection.

WE direct attention to an appeal in another column by Dr. A. P. Stewart and Dr. Glover in what seems a very hard case. If ever the providence of medical men is to be excused for being at fault, it is when overtaken by the calamity of insanity as in this case, where two sisters have to maintain themselves and an insane brother.

ADDED to the other discomforts experienced by our soldiers at the Kassassin camp, it is stated that the place is becoming more and more unhealthy, that diarrhoea prevails to a very disquieting extent, and that dysentery is on the increase. Already a large number of men have been sent back to Ismailia.

NOTWITHSTANDING the great extensions that have been made, and the precautions taken by the authorities, small-pox appears to be spreading in Cape Town and its environs. Much alarm is consequently evinced by the inhabitants. The disease has been clearly traced to the docks.

THE phyloxera has been ravaging the vineyards of the Department of Seine-et-Marne, and to such an extent as to lead to the supposition that the vines must have been under attack for the last four or five years.

AN official despatch from Manilla states that 103 persons died of cholera at that place on September 10th, the number of deaths in the province being 237.

**TYPHOID FEVER AT BANGOR.**—At a recent meeting of the Bangor Local Board of Health, it was decided, owing to the extension of the outbreak of typhoid fever in the district, to erect hospital tents, the accommodation provided by the temporary isolation buildings having proved quite inadequate. The Bishop consented to their erection in his park. With respect to the water which has been so strongly condemned by the medical officer of health as containing fever germs, a report was read from Dr. Muter, South London Laboratory, who, on behalf of the Board, had analysed six samples taken at points where the fever was most virulent. All of these, with a single exception, were reported to be of good quality and drinkable.

## Public Health and Poor Law.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF INSPECTORS TO THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

*Uxbridge Rural District.*—The occurrence of an interesting outbreak of enteric fever at Norwood in the Uxbridge rural sanitary district has been investigated by Mr. W. H. Power. The outbreak occurred in December last in a terrace consisting of thirty artisans' houses, and situated near to Norwood village. Forty years past Norwood had been free from enteric fever, hence a sudden outbreak of this disease in fourteen out of the thirty houses in Harwood-terrace led to some alarm, and it was locally supposed to have been produced by the emanations from a species of manure deposited on the canal side near by, and which consisted largely of the refuse and garbage from London dustbins. But it became at once evident that an outbreak marked by such suddenness and magnitude could not be due to any long-standing cause of this sort, and Mr. Power set himself to work in order to differentiate the circumstances of the houses and persons attacked from those not attacked. The localisation of the disease was curious. Of fifty-one persons living in twelve houses at the lower end of the terrace not one was attacked, whereas out of ninety-seven persons residing in seventeen houses at its upper end as many as thirty-five, or at the rate of 36 per cent., suffered from enteric fever; and, further, a few of the cases were found to have occurred in the previous August and September, and then after an interval of two months there occurred a sudden outburst simultaneously affecting twelve out of the seventeen households. All the various methods by which the infection of enteric fever can be conveyed were then examined in detail, and it became apparent that the infective material from the earlier cases had probably been fostered within the limited area of the upper end of the terrace, and that it had become suddenly operative towards the end of November. The first cases had been treated at home, and their excreta had passed into cesspools, one of which was provided for every two houses, the whole being linked together by overflow pipes. But there was no communication between the interior of the dwellings and these cesspools, and the suddenness of the outbreak pointed rather to milk or to water as the medium of infection. Milk as a cause could readily be set aside, and nothing remained but water. The terrace was said to be supplied from four pumps having four separate wells. One had for some time been out of order, and the houses to which it belonged were supplied from one of the others. But this only reduced the wells to three, two out of which had supplied the infected houses, and it was not easy to see how two wells, separated as they were by a considerable interval and by a brick wall, could have become simultaneously infected. The story, as told by Mr. Power, is a long one; it is illustrated in its very complex details by a diagram of the locality in question, and as a record of a piece of careful scientific work, and of an excellent example of the value of inductive reasoning as applied to investigations of this sort, it is well worthy of study. Mr. Power finally came to the conclusion that the disease could be accounted for if the two implicated pumps drew from one well, instead of from two as he was assured they did, and with a view of being certain as to this, local examination was made, with the result of finding that the suction pipe of the two pumps did, as a matter of fact, lead to one single well. The infection of this single well was soon explained. Just prior to the sudden outbreak a cleaning out of cesspools had been inaugurated, and the contents of one, which had been infected by the early attacks in August and September, were transferred into a newly dug hole distant from the site of a supposed well, but near to and on higher ground than the situation where the now implicated well was actually found to be. Soakage from the cesspit hole would also naturally be carried in the line of natural soakage to the well in question. Thus specific pollution of the well took place, and hence resulted the sudden outbreak of enteric fever in the majority of the houses resorting to it, whilst houses close by and having another supply entirely escaped.

*Ulverstone Urban District.*—The sanitary district of Ulver-

stone, near Morecambe Bay, has some 10,000 inhabitants; and in 1881 there occurred in it fifty-two cases of enteric fever and eight deaths. By far the majority of the cases were concentrated in what is known as the Lightburn district, the remainder being scattered about the town. Mr. Spear, reporting on the outbreak, examined thoroughly into the sanitary circumstances of the population, and arrived at the conclusion that water pollution was the cause of the disease. The town is supplied from the Barrow Corporation Waterworks; but the water thus delivered was so turbid and had been so much complained of that many resorted to other supplies. Close by the Lightburn district, a supply, apparently pure, was available, and it was much resorted to. It was a spring largely fed by surface water percolating the sand and gravel beds of the neighbourhood. But its main feeder was crossed at different points by sewers, and prior to the main outbreak, and during a violent storm of rain, these sewers were known to have been running full under great pressure, so that their contents probably passed into the surrounding soil. And not only so, but this very storm of rain had led to a rush of storm water down a road past a privy containing typhoid evacuations, and thence into the water-supply. Here appeared to be the main cause of the outbreak. As regards the more scattered cases, very similar conditions were found; for many, avoiding the company's water, resorted to suspicious sources—as, for example, a stream, which above the point of intake ran through gardens manured with nightsoil and in close proximity to privies. But at the same time it seems, according to the report, impossible altogether to exonerate the Barrow Corporation water from some share in the mischief, for Mr. Spear reports conditions which fully justify the suspicion with which this water was locally regarded. Thus one reservoir is mainly supplied by streams draining moorland; but they also drain cultivated and manured fields; they are unprotected from chance pollution by man and animals; and the sewage of at least two farmhouses finds its way into them. Grave neglect connected with the privy accommodation of the men employed in connexion with the works is also reported to have led to excrement finding its way into the bed of what afterwards constituted the reservoir. The disclosure of these circumstances has, however, apparently led to their being efficiently dealt with; and it is to be hoped that the Ulverston people may now be able, without any fear of ill results, to resort to the company's water, instead of falling back upon local sources, which appear to be highly dangerous.

#### REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Hastings (Urban).*—A report recently issued by the medical officer of health for the borough of Hastings estimates the present population of this urban sanitary district at 44,239 persons, showing an increase of nearly 2000 upon the number enumerated at the census in April, 1881. This report relates to the three months ending June last, and its statistics imply the satisfactory sanitary condition of the borough during the quarter under notice. The gross annual death-rate did not exceed 16·5 per 1000; the medical officer, however, estimates that 14·8 per 1000 would more correctly represent the true death-rate of the town. This lower figure is arrived at by the exclusion of 28 deaths of non-residents, and the addition of 9 deaths of town residents that were recorded in the work-house and sanatorium, situated outside the boundaries of the borough. In order rightly to estimate whether the lower rate more truly represents the mortality of the Hastings population, it would be necessary to know the medical officer's definition of "non-residents," and how their deaths are identified in the death register. It should, moreover, be borne in mind that the enumerated population of such a watering-place as Hastings would always include a large proportion which, on the same principle, would be classed as "non-resident," for which no correction is made in the estimated population used for calculating the death-rate. However, whether judged by the gross death-rate or by the corrected rate, the mortality statistics of this borough for the quarter under notice are of an eminently satisfactory character. If we except the somewhat fatal prevalence of measles and whooping-cough during the spring, the town appears to have enjoyed an almost complete immunity from zymotic fatality. Infant mortality, generally low in Hastings, was, however, above the average during the spring, owing to the excessive death-rate from diseases of the respiratory organs and the fatal cases of measles and whooping-cough. The medical officer does well in his report to impress upon the

resident householders the primary importance of the sanitary arrangements of the individual houses. We have little faith, however, in the individual action of householders without constant activity on the part of the local sanitary authority, including house-to-house visitations. The public, too, would be wise to insist at watering-places upon satisfactory evidence that the sanitary arrangements of lodging-houses are free from obvious defect. One feature of the Hastings report, which affords the strongest evidence of the abnormal constitution of the borough population, is the fact that the birth-rate was so low as 24 per 1000.

*Newcastle-upon-Tyne.*—According to Mr. Armstrong's report, this borough had a population of 145,675 in the middle of 1881; the births represented a rate of 36·6, and the deaths a rate of 21·7, per 1000. Amongst the deaths due to the specific fevers, there were 52 from scarlet fever, 38 from enteric fever, and 20 from typhus. The use of the fever hospital belonging to the sanitary authority is entered into in some detail. It is an old building which has done admirable service; but it is evidently quite unsuited to the requirements of a sanitary authority for such a borough as Newcastle. In deed, it would appear that, apart from a detached shed, there is only accommodation for the safe treatment of one disease, and yet as many as 69 cases of typhus, 30 of enteric fever, and 72 of small-pox have been received into it during the past year. This evidently accounts for the almost entire absence of scarlet fever cases under isolation. Mr. Armstrong heard of 162 cases of this disease, but only eight were removed to the hospital, and he admits that under existing circumstances the isolation of this disease remains a dead-letter. For several years past measures have been under consideration with a view of dealing properly with this question, but the subject has been again and again put off. The value of such an institution need not be pointed out to the inhabitants of a town which was one of the earliest to provide itself with such a hospital; but something seems wanted to do away with the recurring delays which hinder the efficient action which should be taken with regard to infectious disease in the borough. The story of the outbreak of typhus is interesting. As usual, this disease appeared among the destitute in old and ill-ventilated tenements; it appears to have been promptly dealt with, and isolation of the patients in hospital secured either voluntarily, or, in one instance, by compulsory removal under a magistrate's order. The connexion of enteric fever with the condition of old middens-privies, faulty both in point of construction and as regards scavenging, the presence of autumnal diarrhoea as affected by temperature, rainfall, &c., and many other points, are fully dealt with in the report. One special feature has of late years rendered Mr. Armstrong's reports specially instructive; it is the preparation of a map, on which are marked by dots of different colours all the cases of scarlet fever, enteric fever, typhus, small-pox, and whooping-cough, according to the locality in which they are reported; and it is satisfactory to note that nearly all such cases are voluntarily notified to the officer of health. Thus these maps, when studied year by year, afford a valuable indication of the localities in which the various forms of sanitary work are most needed.

#### VITAL STATISTICS.

##### HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns, 5660 births and 3222 deaths were registered during the week ending the 9th inst. The annual death-rate in these towns, which had been equal to 22·7 in each of the two preceding weeks, declined last week to 19·9. The lowest rates in these towns were 13·6 in Leicester, 15·6 in Bolton, 16·2 in Bradford, and 16·3 in Huddersfield. The rates in the other towns ranged upwards to 24·2 in Newcastle-upon-Tyne, 26·2 in Liverpool, 28·3 in Hull, and 30·2 in Sunderland. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 992, against 1422 and 1307 in the two preceding weeks; 379 resulted from diarrhoea, 81 from scarlet fever, 69 from whooping-cough, 55 from "fever" (principally enteric), 54 from measles, 27 from diphtheria, and 12 from small-pox. The lowest death-rates from these diseases last week occurred in Oldham and Wolverhampton, and the highest in Preston and Hull. The death-rate from diarrhoea showed a generally marked decline last week; although it was again excessive in Hull and Preston. Scarlet fever caused the highest death-rates in Leeds and Nottingham; whooping-

cough in Huddersfield and Blackburn; measles in Hull and Sunderland; and "fever" in Portsmouth and Hull. The 27 deaths from diphtheria in the twenty-eight towns included 17 in London, and 2 both in Salford and Sunderland. Small-pox caused 9 deaths in London, 2 in Newcastle-upon-Tyne, and one in Leeds. The number of small-pox patients in the metropolitan asylum hospitals, which had been 114 and 101 on the two preceding Saturdays, further declined to 91 at the end of last week; only 9 new cases of small-pox were admitted to these hospitals during last week, against 32 and 20 in the two previous weeks. The deaths referred to diseases of the respiratory organs in London, which had been 199 and 202 in the two preceding weeks, declined to 178, which were, however, 17 above the corrected weekly average. The causes of 79, or 2.5 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Norwich, Leicester, and in six smaller towns; whereas the proportions of uncertified deaths were largest in Leeds, Halifax, Oldham, Salford, and Bradford.

#### HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had been equal to 20.0 and 21.1 per 1000 in the two preceding weeks, declined again to 20.1 in the week ending the 9th inst., and exceeded by but 0.2 the mean rate last week in the twenty-eight large English towns. The deaths referred to the principal zymotic diseases in these Scotch towns were 121 last week, and exceeded the number in the previous week by 2; they included 56 from diarrhoea, 29 from whooping-cough, 14 from diphtheria, 11 from scarlet fever, 6 from "fever," 5 from measles, and not one from small-pox. The death-rate from these principal zymotic diseases averaged 5.2 per 1000, and exceeded by 1.0 the mean rate from the same diseases in the large English towns. The highest death-rate from these diseases occurred in Greenock, Glasgow, and Perth. The 56 deaths attributed to diarrhoea showed a further decline from recent weekly numbers, but included 28 in Glasgow, 11 in Dundee, and 5 both in Edinburgh and Greenock. The fatal cases of whooping-cough, on the other hand, which had been 11 and 22 in the two previous weeks, further rose to 29 last week, of which 22 occurred in Glasgow and 3 in Perth. The 14 deaths from diphtheria were within one of those in the previous week, 8 being returned in Glasgow and 3 in Edinburgh. Seven of the 11 fatal cases of scarlet fever occurred in Glasgow, and 4 of the 5 of measles in Dundee. The 6 deaths referred to "fever" showed a further decline from recent weekly numbers—they included 3 in Perth and 2 in Glasgow. The deaths referred to acute diseases of the lungs in the eight towns, which had been 60 and 80 in the two previous weeks, declined again to 61 last week, and were 28 fewer than those attributed to the same diseases in the corresponding week of last year.

#### HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had risen from 20.1 to 27.3 in the three preceding weeks, further increased to 27.6 in the week ending the 9th inst. During the first ten weeks of the current quarter the death-rate in the city averaged 22.5 per 1000, against 18.6 in London and 17.7 in Edinburgh. The 184 deaths in Dublin last week showed a further slight increase upon the numbers returned in the three preceding weeks; they included 17 which were referred to diarrhoea, 8 to "fever," 1 to measles, 1 to scarlet fever, 1 to diphtheria, and not one either to small-pox or whooping-cough. Thus 28 deaths resulted from these principal zymotic diseases, against 27 and 28 in the two previous weeks; these were equal to an annual rate of 4.2 per 1000, while the rate from the same diseases was 3.1 in London and 2.0 in Edinburgh. The deaths referred to diarrhoea, which had steadily increased from 5 to 19 in the six preceding weeks, were 17 last week. The fatal cases of "fever" (enteric, typhus, or simple), which had been 6 and 3 in the two previous weeks, rose to 8 last week, and exceeded the number returned in any week since March last. The death-rate from fever last week in Dublin was equal to 1.20 per 1000, and was more than seven times as great as that which prevailed in London during the same period. The deaths both of infants and elderly persons almost corresponded with those returned in the preceding

week. The causes of 22, or nearly 12 per cent., of the deaths registered during the week were uncertified.

#### MORTALITY STATISTICS IN THE WEST INDIES.

It is much to be regretted that the vital statistics relating to our West Indian Colonies are not issued collectively and upon some uniform basis. Under present arrangements these statistics are published at various dates and in every variety of form for the numerous islands and provinces which comprise our colonies in the West Indies. So far as may be judged from the desultory, and in many cases most imperfect, statistics which from time to time come before us, it cannot be doubted that the health of these colonies, measured by their death-rate, has materially improved in recent years. A report has been recently issued by the Registrar-General of Grenada which affords the means for estimating the health condition of this island during last year. The island of Grenada had at the census in April, 1881, an enumerated population of 42,403 persons, which had, according to the Registrar-General's estimate, increased to 42,788 by the end of the year; this estimate gives an average density of 321.7 persons per square mile. The birth-rate, calculated on the population at the beginning of the year, instead of the middle of the year, which would have been more correct, appears to have been as high as 43.5 per 1000. This rate is inclusive of still-births, which are registered both as births and deaths. Especial attention is called to the fact that more than half the births (52.3 per cent.) are illegitimate. This large proportion is attributed partly to the overcrowding in houses inhabited by the lower classes of the colony, and partly to "the shameless indecency with which many parents of the peasant class permit their children to go without clothing" in defiance of the law. The death-rate was equal to 27.7 per 1000, and all but corresponded with the mean rate in the preceding ten years. The return as to the causes of death is of the most meagre description, owing in great measure to the difficulty of obtaining satisfactory information on this point. Indeed, in nearly ten per cent. of the recorded deaths the cause was not stated. Zymotic diseases are stated to have caused 221, or 15 per cent., of the deaths; but beyond a vague reference to the fatal prevalence of whooping-cough, and a quotation from some remarks furnished by the colonial surgeon, who says that "the endemic fever of the tropics" prevailed, but not to a great extent, during the latter half of the year, no details of this zymotic fatality are given. With reference to infant mortality, it is stated that the deaths of infants under one year of age was equal to 188 per 1000 of the registered births. Excessive as is this rate of infant mortality, it is not higher than might be expected, bearing in mind the remarkably high proportion of illegitimacy. It is urged that if the production of medical certificates were made compulsory in the case of deaths of children, the rate of infant mortality would be much reduced. There are obvious difficulties in the way of making the production of such a certificate compulsory, but formal inquiry into the cause of all uncertified deaths would probably have an important effect in the desired direction. We have, however, yet to obtain this important reform at home before we can fairly urge its adoption in Grenada.

#### THE SERVICES.

A reinforcement of the Army Hospital Corps, consisting of sixty non-commissioned officers and men, embarked for Egypt in the P. and O. steamer *Nizam* on the 13th inst., Surgeon-Major W. C. Boyd being in medical charge of the troops proceeding thither.

Deputy Surgeon-General Fox has been ordered to proceed from Chatham to Ismailia to superintend the hospital service at the base of operations.

Surgeon-Major W. T. Martin is under orders to embark for Egypt at an early date.

The staff of lady nurses with the expedition is to be increased by five additional sisters.

Brigade-Surgeon G. S. Ogg, Madras Medical Service, has been appointed to officiate as Deputy Surgeon-General during the absence with the expeditionary force in Egypt of Surgeon-General Colvin Smith, M.D.

Surgeon MacGeogh embarked on board the s.s. *Palmyra* on the 13th inst. in charge of drafts ordered to Cyprus.

**ARMY MEDICAL DEPARTMENT.**—Deputy Surgeon-General John Phillips Cunningham, M.D., has been granted retired pay, with the honorary rank of Surgeon-General; Brigade Surgeon Adam Graham Young, from half-pay, to be Brigade Surgeon; Surgeon-Major Alfred Frederick Strafford Clarke, M.D., has been granted retired pay, with the honorary rank of Brigade Surgeon.

**RIFLE VOLUNTEERS.**—1st Huntingdonshire: Surgeon and Hon. Surgeon-Major Dennis Adams and Hon. Assistant-Surgeon George Robinson resign their commissions. —1st Devonshire: George Chapman Steele-Perkins, gent., M.B., to be Acting-Surgeon. —1st Newcastle-on-Tyne and Durham: William Mearns, gent., M.A., M.D., to be Acting-Surgeon. —1st Dorsetshire: Surgeon Henry Tizard, M.D., the resignation of whose commission was notified in the *London Gazette* of July 4th, is permitted to retain his rank, and to wear the uniform of the corps on his retirement. —2nd Gloucestershire: Surgeon Edward Waddy resigns his commission. —3rd Monmouthshire: Samuel Butler Mason, gent., to be Acting-Surgeon. —1st Inverness-shire (Inverness Highland): Acting-Surgeon John Simpson, M.D., resigns his appointment. —1st Kent: Acting-Surgeon Adam Young to be Surgeon. —2nd Lanarkshire: Surgeon James Loudon, M.D., is granted the honorary rank of Surgeon-Major.

**ADMIRALTY.**—The following appointments are announced: Staff-Surgeon Thomas Conroy to the *Dasher*; L. Ffrench-Mullen to the *Garnet*, commissioned; Staff-Surgeon James William Fisher, M.D., has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet, with seniority of the 2nd inst.

## MEETING OF THE FOURTH INTERNATIONAL CONGRESS OF HYGIENE AT GENEVA.

It must at once be recognised that the Congress has been a great success. It numbered more than 400 members, and no less than twenty-four different nationalities were represented. There were members who came expressly to assist at the Congress from Algeria, Austria, Belgium, Brazil, Bulgaria, Basutoland, Denmark, England, Germany, Greece, Holland, Hungary, Italy, Mexico, Ontario (Canada), Portugal, Poland, Roumania, Servia, Switzerland, Spain, Sweden, Turkey, and the United States of America. Many of the principal Governments—France, Germany, Russia, Austria, Spain, Italy, &c.—sent official delegates; while many leading municipalities—Paris, Berlin, Frankfort, Seville, Madrid, Turin, La Haye, &c.—also appointed special representatives. The Board of Health of Ontario (Canada) was represented by Dr. C. W. Coverton, but not a single English town or administration sent a representative. We noticed that two gentlemen from the Local Government Board were present; but they came in their private, not their public, capacity. Under such circumstances it is not surprising that many complaints were uttered at the lack of friendly feeling on the part of the English nation. As the leaders in sanitary reform, we ought to take an active part in assisting this great effort on the part of European nations to spread and equalise sanitary reform. With such speakers as M. Pasteur and M. Paul Bert, it is impossible to say that even the wisest among us have nothing to learn; while, on the other hand, we have everything to gain by coming to an international understanding on sanitary matters. Thus Professor Brouardel, after a most able paper read in the third section, carried a resolution, subsequently confirmed by the general assembly, that at the next International Sanitary Congress the delegates from each nation should bring a summary of the laws affecting the adulteration of provisions, so that adulterated food, condemned in one country, should not be exported and sold with impunity in another. Our recent experiences with respect to preserved peas imported from France, and coloured with copper, points to the necessity of such international understanding. Dr. Brouardel insisted that falsifications were now carried out with the aid of enormous capital and great chemical knowledge. The employment of salicylic acid to preserve beer, wine, milk, fish, vegetables, &c., was especially dangerous. It might be argued that the quantity used was insignificant; ten centigrammes in a litre were supposed to suffice to prevent wine from turning sour; but he had often found an

entire gramme in the litre. The fact was that the same substance was manipulated by different people. Perhaps the wine-grower himself, feeling a little anxious about his wine, would add a little salicylic acid; then the wholesale merchant would, in his turn, interfere; and finally the retailer came with a third dose, each probably imagining that he alone had resorted to this dangerous expedient. Thus, when the bottle came to the unfortunate consumer it had been thrice dosed, and perhaps thrice overdosed. The effect of this form of slow poisoning was most difficult to trace to its origin, unless some accident revealed the cause. Dr. Brouardel suggested, however, that by the analysis of urine the unconscious absorption of salicylic acid could in most cases be detected. The worst feature in the use of this acid for the preservation of food arose from the fact that there was no uniform rule as to the quantity which could be taken with impunity. A healthy child might take even five grammes in one day without any very serious consequence; whereas an adult invalid, especially if suffering from any renal complaint, would require eight days to eliminate such a dose. This was but one illustration of the dangers attending the unscrupulous use of scientific means to promote the interests of certain traders; and it was of little use checking the evil in one country if the suspicious articles could be sold with impunity on the other side of the frontier.

This is but one example of the style of discussions that prevailed, and of the practical advantages to be derived by a nation such as England, when represented at congresses of this description. The discussions were divided into five separate sections, and the work and pleasures of the Congress lasted every day from nine in the morning till midnight, with barely time allowed for meals. We cannot now give a summary of the debates. We may, however, express in the name of the English members who were present our high appreciation of the cordial and most hospitable reception accorded by the organisers of the Congress and the Swiss Government. It was scarcely possible to believe that a nation so restricted in its area, so limited in its population, could have given its foreign guests so magnificent a welcome. The first night there was an official reception and concert in the vast saloons of the new theatre—one of the model theatres of Europe so far as ventilation is concerned. On Tuesday evening, Professor A. de Candolle, son of the renowned botanist, and himself a man of high scientific attainments, received the members of the Congress at his mansion, near Geneva. The vast gardens and their botanical treasures were brilliantly illuminated, while within the members of the Congress joined with the *élite* of Geneva society in the enjoyment of a bountiful supper. The following evening there was a similar reception at the hydrotherapeutic establishment of Champel-sur-Arve on the outskirts of Geneva. But of all days Thursday was the most enjoyable. The Swiss Government had provided the finest steamer of the lake, the *Mont Blanc*, and three hundred and fifty members of the Congress embarked at nine in the morning, following the southern coasts of the lake till we reached Evian-les-Bains. Here a sumptuous lunch was provided by the directors of the establishment; and, after a few speeches and a stroll, the Congress once more went on board. But even at this moment business could not be altogether forgotten. In spite of the loud tones of the band which accompanied the expedition, and the general desire of the company to enjoy the unrivalled surrounding scenery, the Italian delegates insisted on holding a meeting in the principal cabin to discuss cremation. Fortunately the speeches were short. The effects of the lunch and the joys of the holiday were scarcely in harmony with this gloomy subject. After visiting the extreme end of the lake, where the Rhone brings the mud of the mountains into the clear waters, and then stopping a moment to contemplate the historical castle of Chillon, we landed at Montreux, saluted by peals of artillery. At the Kursaal the theatre was converted into a banquetting-hall, the stage being occupied by local bands and glee societies, who played and sang alternately during the dinner and between the speeches, in which the members of the Swiss Government, the Federal Council, and the local administration took a prominent part. When the banquet was over it was already dark, and the members of the Congress were agreeably surprised to find the whole line of the coast illuminated in their honour. The steamer also was gaily bedecked with garlands of lamps of many colours, while on the still waters smaller

craft flitted here and there, burning Bengal fire or carrying numerous lamps that reflected their colours on the transparent lake. The Congress once on board, the steamer put off a little distance from the pier, and then commenced a display of fireworks, starting simultaneously from the gardens of the hotels that line the shore, and from points high up in the mountains. Against the dark background of the black mountains, the Bengal fire enabled us clearly to discern the elegant hotels and villas poised some three thousand feet above us at Les Avants and at Glion. The church steeple of Montreux was brightly lit. Vevey and the surrounding villages joined in the festivities. For some two or three miles along the coast it was one blaze of light, and rocket after rocket shot up towards the sky; while the roar of the cannon, the stirring strains of the British national anthem (played by a powerful brass band), the cheers from the ship and the shouts from the shore, all helped to conclude a reception unsurpassed for its cordiality, and which will for ever remain deeply impressed in the memory of the guests. Nothing could have more conclusively proved the public spirit of the Swiss population, the interest they have taken in the work of the Congress, and the high honour they wished to confer on their distinguished visitors. Another evening reception, concert and supper, on the Friday, at the mansion of Mde. Eynard, and a farewell banquet on Saturday evening, concluded the festivities of the Congress; and certainly, whatever services the members may have rendered by their work during the week, they have been amply rewarded by the cordiality and unbroken harmony of the reception accorded to them. If sanitary science can always be propagated under such auspicious circumstances, it will certainly become the most popular of all sciences.

### PROSECUTION FOR FORGERY OF PRACTITIONER'S NAME TO CERTIFICATE OF DEATH.

AT the Thames Police Court, on September 2nd, before Mr. Lushington, William Henry Viner, of 123, St. George's-street, East, appeared to answer a summons issued at the instance of the Medical Alliance Association, charging him with the wilful forgery on the 21st August ult., of a certificate concerning the death of a child named Annie Niendorff. Mr. C. J. C. Pridham, solicitor to the Association, appeared for the prosecution; and Mr. Besley, barrister, for the defendant.

Mr. Besley took a technical objection to the summons on the ground that no one but the Superintendent Registrar of the District had the power to issue the same under the Act; but after a lengthy argument from the learned gentlemen engaged, it was over-ruled by the magistrate.

The facts of the case as proved disclosed a very serious offence, and Mr. Pridham, in opening the case, stated it was the gravest charge of the kind in which he had ever been instructed to prosecute. It appeared, from the evidence of the mother, that the child Niendorff fell ill about the 17th or 18th August, and was taken by her to a medical hall and dispensary at 123, St. George's-street, East, kept by the defendant in the name of a registered medical practitioner named Berdoe. The child was seen there on two occasions by the defendant, who represented himself to the mother as being properly qualified, and whom the mother believed to be Dr. Berdoe, as that name appeared over the door. On the 21st August the child died, and the mother applied at the dispensary for a certificate of its death. The defendant thereupon wrote and signed in the mother's presence a certificate, in which he stated that he had attended the child Niendorff, certifying the cause of death as pneumonia and convulsions, and signed the name of Edward Berdoe, M.R.C.S., L.S.A., 123, St. George's-street, East, and gave the same to the child's mother.

Formal evidence was given by the district registrar of the receipt of the certificate from the mother, and of his having entered the death in the register as certified by Dr. Berdoe.

Dr. Berdoe was then examined, and stated that he had never seen or attended the child Niendorff, or certified the cause of death. The signature to the certificate was a forgery.

In cross-examination the witness stated he had sold the

business of a chemist and druggist, at one time carried on by him in connexion with his medical practice at 123, St. George's-street, East, to the defendant in October, 1879. Since that time his connexion with the place and the defendant had entirely ceased. He had desired the defendant on several occasions to remove his name from the fascia, which he promised to do, and was unaware of the fact that it was still up there until so informed by the solicitor for the prosecution. He had never given the defendant on any single occasion any authority to act for him or to use his name. The defendant had made overtures to him to attend there and see patients, which he declined.

Mr. Lushington, in giving judgment, said the defendant had committed an offence of a most serious kind. It had been suggested by the defendant's counsel that he had no power to deal with the summons. He felt some difficulty in doing so, not on the technical ground put forward by Mr. Besley, but because he was in some doubt whether he ought not to commit the defendant for trial. However, as he had not been requested to do so by the prosecution, he should impose the severest penalty he had power to inflict. He ordered the defendant to pay a fine of £10, and £5 5s. costs, or to be imprisoned for three months in default.

"Audi alteram partem."

### THE ABSENCE OF SCURVY IN THE "EIRA" ARCTIC EXPEDITION.

To the Editor of THE LANCET.

SIR,—I cannot help thinking that the suggestions which have been made as to the probable explanation of the absence of scurvy in the *Eira* expedition are founded upon a misapprehension of the circumstances in which the crew were placed. If Mr. Neale's most interesting narrative in THE LANCET of August 26th be carefully read, it will be seen that the crew were abundantly supplied with vegetables to eat along with their ample allowance of meat. They averaged half a pound of vegetables to each man per diem. I suppose there are few of us who eat more than this. The experience of the *Eira* expedition, therefore, so far from being in the least degree contradictory of the generally received opinion as to the cause of scurvy, lends the best possible support to its correctness. Had scurvy occurred in the circumstances described, the fact would indeed have been very remarkable.

Mr. Neale has been good enough, at my request, to record (THE LANCET, Sept. 2nd) certain particulars respecting the mode of preservation of the vegetables which were saved, and the state in which they were consumed. These details appear to me to be of great importance, and will need to be carefully noted in the preparations for any future expeditions.

I am, Sir, yours faithfully,

Grosvenor-street, W., Sept. 1882.

THOMAS BUZZARD.

### AUTUMNAL DIARRHŒA.

To the Editor of THE LANCET.

SIR,—Allow me to call the attention of medical men to the prevalence, in autumn, of sickness and diarrhœa, which is put down to fruit. Autumn is the time for ripe fruit, but because diarrhœa is also prevalent at the same time we must not blame fruit for it. If we carefully examine each case which comes before us, we shall find that fruit plays a very small part in it. The real cause is the heat of the weather and the animal food taken. I will now describe an ordinary case and its usual cause. The patient goes to bed all right and in his usual health; he is awake about two or three hours after retiring by a sharp gripping pain across the abdomen, he also feels blown up, and keeps eructating mouthfuls of flatulence and acid fluid. Purging soon sets in and offensive liquid stools are passed. Vomiting next occurs of an acid acrid fluid. There may be cold shivers and hot flushes, which are followed by a feeling of great prostration. This continues during the night and best part of next day. Food, especially if warm, only makes matters worse.

We are called in, and find the patient has a quickened pulse, foul tongue, yellow conjunctivæ, a dejected look, and he complains of feeling very low. Cross-questioning nearly always brings out the fact that at supper-time he had a good meal, consisting of f-i-h, flesh, or fowl. The most offending meat is pigs' flesh in some form, chiefly as pork; then comes veal, and lastly plain beef or mutton. The fish most commonly giving rise to this sickness are salmon, mackerel, lobster, and crabs. A few cases can be traced to high cheese or to eggs. Cucumber may help, especially if dressed in the usual way with salt and pepper. But never have I seen a case where a purely vegetarian supper has been taken. The treatment is very simple: allow spoon food every four or five hours, it must not be hot, but lukewarm; enjoin rest, and give a mild sedative of some kind. I am, Sir, your truly,

T. R. ALLINSON, L.R.C.P. Ed.

Kingsland-road, E., Sept. 12th, 1892.

## VOLUNTEER AMBULANCE SERVICE.

To the Editor of THE LANCET.

SIR,—As I have had numerous inquiries as to the formation and equipment of volunteer ambulance detachments, I shall feel obliged by your insertion of the following particulars in your journal, for the information of those who have not already formed such detachments, and who are desirous of doing so.

The senior regimental surgeon, before instructing his class, should first make himself efficient by passing the Examination for Volunteer Medical Officers. The books required for this examination are: (1) "Parkes' Hygiene," by Professor De Chaumont; (2) "The Surgeon's Pocket-book," by Surgeon-Major Porter; (3) "Gunshot Injuries," by Professor Longmore; (4) "Manual of Instructions for Army Hospital Corps;" (5) "Manual of Exercise for Stretcher-bearers and Bearer Company;" (6) "Army Medical Regulations."

As soon as the medical officer feels himself prepared for the examination he must apply, through his adjutant, to the commanding officer of the regiment to be examined. In due course he will receive an intimation from the principal medical officer of his head centre to appear for examination. The examination is conducted by three officers of the Army Medical Department, *vis à voce*, thoroughly practical, and embraces the prevention and treatment of diseases peculiar to soldiers in camp and on field service. The following are the most important points:—(1) Sanitation of camp and precautions against disease; (2) sanitation for troops on the line of march; (3) general treatment of diseases common in camp and on field service; (4) first assistance to wounded on field of battle; (5) their removal and transport to field hospitals.

On passing this examination the medical officer will receive a certificate of proficiency in the following words:—"We certify that —, of the — (who is registered under the Medical Act of 1858 as qualified to practise medicine and surgery in Great Britain and Ireland), is well acquainted with the nature and intended application of the various articles composing the equipment of army hospitals in the field, and with the authorised means for the transport of sick and wounded soldiers, and the proper modes of employing them. We also certify that he has a competent knowledge of the treatment of the wounds and injuries to which troops are liable in the field, particularly with regard to the special circumstances of campaigning; and that he is acquainted with the duties to be performed by army medical officers in camps and bivouacs, and during marches, as detailed in the Regulations for the Army Medical Department, Revised Army Regulations, vol. vi. Signatures of Board of Examining Officers— Station— Date—"

I may here mention that medical officers by thus obtaining this certificate of proficiency will earn for their respective corps the special capitation allowance of £2 10s.

Assuming, then, that the medical officer has obtained his certificate of proficiency, and wishes to form bearer detachments, his first duty, of course, is to obtain the permission of his commanding officer, then to select two men from each company in his battalion to be trained as stretcher-bearers.

Thirteen lectures must be given of not less than an hour and a half's duration each, at which each bearer must be present not less than eleven times. The lectures are given in accordance with the instructions issued by the Volunteer Ambulance Department, a synopsis of which can be obtained by applying to Lieut. Maclure, Volunteer Ambulance Department, Army Medical Department, 6, Whitehall-yard, London, S.W., and from whom also can be obtained the stretchers and diagrams required. The field companion, haversack, and water-bottles are obtained from Messrs. Savory and Moore, New Bond-street, London. As soon as the class has been duly trained the surgeon must apply to the principal medical officer of the district, who will cause the bearers to be examined, and if found proficient, will each receive a certificate on Army Form, E. 596. Two volunteers from each company who have so qualified will be selected by the commanding officer of the corps, on the recommendation of the medical officer, to be the stretcher bearers of the corps and to wear the Geneva Badge on their right arm. These badges can be obtained from Lieutenant Maclure also. I believe, as a rule, commanding officers are glad to do all in their power to forward this movement, and I can only speak of my own good Colonel Sir William Worsley, Bt., and his able adjutant, Major Hedley, as patterns in this respect.

I cannot conclude these few remarks without gratefully acknowledging the great assistance and information I received from Surgeon W. H. Platt, Treasurer, and Lieutenant Maclure, Secretary of the Volunteer Ambulance Department, when I was commencing this work myself.

I am, Sir, yours truly,

JOHN WM. TAYLOR, M.D., D.Sc.,  
Surgeon 2nd Battalion North York Rifle Volunteers.

Scarborough, August 28th, 1892.

## A CASE FOR HELP.

To the Editor of THE LANCET.

SIR,—May we ask your readers to consider an appeal which we have to make on behalf of a medical man, late of Buntingford, Mr. Charles Gaffney, who has to be maintained in an asylum by two sisters, who have much difficulty in supporting themselves by a lodging-house in the Fulham-road. If some means of helping them is not quickly forthcoming, no alternative will remain but that of making him a pauper lunatic. Their case is the harder now as one of the sisters is ill with bronchitis, and their principal apartments are unoccupied. The merit of the case is further illustrated by the fact that two kind grants have been made by the British Medical Benevolent Fund—one of £30 in 1881, and one of £18 in 1882. The mental disease which has disabled Mr. Gaffney has existed for nearly fifteen years. During part of this time he has been supported out of some means of his own, which have long been entirely exhausted, and he is now dependent on two sisters, who are themselves very hardly pressed and confronted with the workhouse. A few kindly subscriptions at this adverse moment might help two good sisters to keep an insane brother, and brighten what seems a very dark look-out.

We are, Sir, your obedient servants,

A. P. STEWART, M.D.

J. G. GLOVER, M.D.

## HOMES FOR INEBRIATES.

To the Editor of THE LANCET.

SIR,—In his second annual report the able Inspector of Inebriate Retreats strongly urges the need for the opening of the proposed Dalrymple Home for Inebriates. Though indefatigable in their efforts, the committee have received very limited pecuniary support. They, however, hope to be able to commence operations before the end of this year. The triumphant progress of temperance missions is daily recorded by the Press, and it is to be hoped that the unselfishness and devotion which ought to be the motive power of such a crusade will be attested by liberal financial support to the projected Dalrymple Home as an attempt at

the reformation and cure of the many habitual drunkards whose whole system has become so diseased by alcohol that absolute seclusion from temptation is essential to restore their shattered nerves and their utterly broken down will power. Among the office bearers of the proposed Home are the Archbishop of Canterbury, the Duke of Westminster, Lord Shaftesbury, Sir Thos. Watson, Sir Henry Thompson, Dr. Andrew Clark, and Dr. B. W. Richardson. £3000 is still needed. Donations and also annual subscriptions will be thankfully received by the chairman, Canon Duckworth, Dr. Alfred Carpenter, J.P., Croydon.

I am, Sir, your obedient servant,

NORMAN KERR, M.D.,

Hon. Sec., Dalrymple Home.

Grove-road, Regent's-park, N.W., September 9th, 1882.

## CLINICAL THERMOMETRY.

To the Editor of THE LANCET.

SIR,—I wish to call your attention to a possible source of error in clinical thermometry. I have one of Maw's seven-inch hospital thermometers, and I accidentally discovered that by gentle compression of the mercurial bulb I was enabled to make the index rise some three or more degrees; such pressure the bulb might easily be subject to in the axillary space, especially if the arm be pressed close to the side.

I am, Sir, yours truly,

Brighton, Sept. 5th, 1882.

J. M. E. SCATLIFE, M.D.

## NERVE-VIBRATION: A CAUTION.

To the Editor of THE LANCET.

SIR,—Will you permit me as the originator of the method of "Nerve-vibration by precise percussion" in the treatment of certain forms of nervous disease and disturbance to warn the profession against the conversion of this method into a "cure" or "system"—of which we have already too many mischievous specimens—by placing my percuteurs in the hands of patients and their friends. As well, and more safely, might those gentlemen who are pursuing this course supply their clients with scalpels, galvanism, electricity in its various developments, and hypodermic injections, which have been reduced to the level of nostrums by this reckless procedure.

I must earnestly protest against the abuse of nerve-vibration by a like policy. My protest is made not less in the interests of the sufferers from diseases than in that of professional propriety. Nerve-vibration is a potent agency for good or evil, as it happens to be applied. It is exceedingly difficult of application, and requires to be employed with the greatest care and intelligence. A thorough knowledge of the anatomy and physiology of the nervous system is indispensable for its safe and successful use. If medical men have not the time or do not care to administer it themselves, they will do wisely to leave it alone.

Already I have seen harm ensue from its misuse, and I therefore feel bound to give this warning to medical men who having heard of cases which have been benefited are purchasing or borrowing instruments for their patients to use! Nothing but disappointment can result from this indiscretion.

I am, Sir, yours truly,

Welbeck-street, W., Sept. 1882. J. MORTIMER GRANVILLE.

## GLASGOW.

(From our own Correspondent.)

MR. GEO. A. D. MACKAY read an interesting paper at the recent annual meeting of the Sanitary Association of Scotland, in which he reviewed the improvement which had been effected in the public health in Greenock since the local authority had obtained special Parliamentary powers. Before 1876 the general mortality of the town was higher than in any other town in Scotland; while the special mortality in certain of the closes and blocks of buildings was appalling—40 to 67 per 1000 of the population on an average of ten years. The removals to the hospital and fever-house were so numerous that they were equivalent to

the whole population of the locality being sent there in the space of twenty-five years. The mean annual death-rate during the period 1875–75 was 31·24 per 1000; while in the five years 1876–80 it was 24 per 1000, and last year 22·14. Contrasting the mortalities of these periods, this improvement is equal to 621 lives saved. This change has taken place notwithstanding the many physical drawbacks from which Greenock suffers—a bad site, a proverbially rainy climate, irregular and narrow streets, extreme concentration of population, and a smoky atmosphere. The figures I have quoted are excellent, and show that the Greenock authorities have not fallen behind in the march of sanitary progress.

The position of surgeon to large industrial establishments is becoming anything but an enviable one in this part of the country. This is in part due to the assertion by the workmen, in many quarters, of their right to elect their medical officer themselves, in consideration of the fact that he is paid by sums retained periodically from their wages; power is thus transferred from the masters to the men, a change which does not seem to have a very elevating influence on the tactics adopted by contending medical candidates in many instances. For example, we have at present a contest going on in Glasgow for the surgeons for certain iron-works, a place of some pecuniary value, for which about forty applicants are striving, some of them after a fashion hitherto supposed to belong exclusively to parliamentary or municipal elections; thus, the works are placarded with bills advising the men to "Vote for ———"; and handbills are circulated asking "Why vote for ———? Because he is a gentleman; because you all know him" and so on. It is to be hoped that it is the injudicious friends of the candidates, and not the candidates themselves, who are at the bottom of all this.

Sounds of preparation for the coming winter are heard in all our numerous local medical schools. At the University there is no change of any importance to chronicle. At the Royal Infirmary the managers have shown by their laudable energy and liberality that they have the good of their medical school at heart, the new block of buildings which has been erected, to be devoted entirely to the purposes of the school, providing almost a superabundance of accommodation for the lecturer. Such enterprise indicates faith in their future. The staff of the Western Medical School has been increased by the appointment of Mr. W. Limont as lecturer on Physiology. At Anderson's College things remain pretty much as they were last year. The calendar just issued by this college is, in a certain sense, very instructive reading. The interest lies, as usual, in the statistics. On looking at the statement of the number of students in attendance last year, winter and summer, it is found that the grand total amounts to 2405. These figures are startling, and to the uninitiated give the impression of a very extensive concern. Even after deducting nearly 900, the number attending the popular evening classes, and about 1100, the number said to attend the non-medical classes, we have a medical school with an alleged strength of over 400, a statement which we in Glasgow know to be utter nonsense. And the manner in which this result is achieved is delightfully simple; it is the old trick (for it is nothing else) so familiar to country theatrical managers who have to make a handful of "supers" do duty for the British Army by effecting numerous entries and exits; each student is reckoned in once for every class he attends, both summer and winter. A student, therefore, who takes, say four classes in winter and two in summer, finds that he plays rather an important part in these statistics. This ready method of "magnifying one's office" is really a credit to the author.

There was another unfortunate death from chloroform in the Royal Infirmary the other day. The operation for which it was given was, as is most commonly the case, a very trifling one, the removal of some smashed toes. Doubtless a report of the case will be forthcoming.

The salary of Dr. James B. Russell, medical officer for the city, has been raised from £700 to £850 per annum, and is thus brought more into accord with the many and important duties of the office and the services Dr. Russell has already rendered to the city.

It is freely reported both here and in Aberdeen that Dr. William M'Ewen of this city is standing as a candidate for the vacant chair of surgery in Aberdeen University. I believe I am right, however, in saying that Dr. M'Ewen has given up all intention of joining in the contest. Possibly the loss of hospital practice which such an appointment

would, in the first instance at any rate, involve, may prevent such outsiders as wish to practise as pure surgeons from applying for the vacant post.

### SCOTTISH NOTES.

(From our own Correspondent.)

SINCE I last wrote, the vacancy in the surgery chair at Aberdeen has given rise to much speculation in the North of Scotland, and quite a crop of candidates is spoken of. It is not too much to say that some of the local gentlemen who have come forward, or allowed their names to be mentioned as candidates, have no claim whatever to such an honourable position, their surgical fame being quite imaginary. When it is mentioned that Dr. Ogilvie Will is not in the field to oppose Dr. Alex. Ogston, it will be understood that the latter gentleman has the almost undivided support of the local profession, and I know that Dr. Ogston has the enthusiastic support of almost the whole professorial staff, though the minority, from its activity and position, is by no means powerless. It is gratifying to hear that Dr. Ogston has returned from his holiday much improved in health, and feeling quite fit for the duties of the chair. If his fitness as a teacher equals the testimony offered by his students at the infirmary and others, his scientific labours should render it difficult for the Home Secretary to overlook his claims, as compared with the other candidates now in the field. So far, the only declared candidate out of Aberdeen is Dr. Cantlie, Demonstrator of Anatomy and assistant-surgeon at Charing-cross, and if the partiality shown by the Charing-cross authorities for Aberdeen graduates can be reciprocated, an opportunity is now offered. One reason for the paucity of strong candidates from a distance is the fact that Dr. Pirrie's place has been already filled at the infirmary, and the directors do not guarantee a place on the staff for the professor if he is not already there. This is peculiarly unfortunate in the interest of the university, as it is not unlikely that the distinguished surgeon of whom I have already written, and possibly other suitable men, may decline to compete for this particular reason. The arrangement may not have been preconcerted, but it has a very suspicious aspect.

It has been arranged for Professor Young of the Glasgow University, to deliver the course of lectures at Aberdeen during the ensuing session, under the Thomson bequest. The course, addressed chiefly to students of divinity at the Free Church College, is also open to the public, and deals with some special branch of natural science. Hitherto the lectures have been successful, and are now looked forward to with considerable interest.

The Asylum Board at Montrose have commissioned a local well-known artist to paint Dr. Howden's portrait, as a memento of the late centenary celebration, and as an evidence of the esteem in which he is held by his directors.

From the report of the Tweed Commissioners, it appears that the fungoid disease has, during the past year, affected an enormous number of salmon in that river. As compared with what was in 1880 considered an excessive mortality, the number of dead fish removed during the past year is grievously disappointing. The 2907 in 1881 seemed favourable after 5222 had been extracted in 1880, but this year the total is 14,627. The proportion of spawn and unspawned fish has varied largely during each year. The amount of river pollution from the various works is still undiminished, and in one case a prosecution has been instituted against the offending proprietor. As the disease has now spread to the Tay and other salmon streams, its prevention has become a serious question for the Fishing Board.

A boy about four years of age is said to have died at Stirling a few days ago from having eaten, while at play, the fruit of the deadly nightshade, *atropa belladonna*. Vomiting and delirium were present, and the boy was removed to the infirmary, where he died at the end of about twenty hours.

The highly fatal epidemic of scarlet fever at Cupar is now lessening in intensity, and the cases are rapidly decreasing in number. I was misinformed as to the presence of typhoid fever, and on direct inquiry learn that since the introduction of a system of water-supply, a few years ago, this disease

has been seldom present, notwithstanding the insanitary state of many parts of the town, and notably that in which the present epidemic of scarlet fever has most located itself. Dr. Whitelaw's action and intelligent interference have been quite exemplary.

### IRELAND.

(From our own Correspondent.)

THE examinations in the Faculty of Medicine of the Royal University of Ireland commenced last Monday in the Exhibition Palace, Dublin, the subjects being Anatomy and Physiology on the first day.

Surgeon-Major George Shaw, who was killed on the 28th ult. at Kassassin Lock, Egypt, was the second son of the late Mr. Christopher Shaw, a Dublin surgeon. The deceased, who was unmarried, was only thirty-five years of age; and his loss is much regretted by a very wide circle of friends both at home and abroad, to whom he was endeared by many deserving qualities.

By the lamented death of Professor Leith Adams, F.R.S., a vacancy has taken place in the Chair of Natural History and Botany in the Queen's College, Cork. Applications for the office will be received up to the 20th inst., the emoluments of which are partly obtained from the fees of students attending the classes and an endowment fund of £292 yearly to the chair.

The First Professional Examination of the Royal College of Surgeons under the new scheme will be held at the College on October 23rd next and following days. All students who commenced their medical studies on or after October, 1880, can present themselves for this examination on producing evidence of having passed the Preliminary Examination, and of having been engaged in medical study for at least nine months subsequent to registration as medical students. The examination will include Physics (if not passed at the Preliminary Examination), the Elements of Chemistry, Botany, Anatomy (Human Osteology), and Practical Pharmacy. The fee for this examination will be ten guineas.

No examinations for the licences of the College of Physicians took place last month, and it is not expected that any will be held this month either, even should a special examination be applied for. The annual election for president, vice-president, and other office-bearers will be held on St. Luke's day, the 18th proximo.

An "unfortunate" named Smith was killed last week in Dublin by a soldier who knocked her down and then made a thrust at her face with a short stick. Deceased was admitted into hospital in a state of insensibility, from which she never rallied. A post-mortem examination showed that there was a punctured wound of the left eyelid which passed through the orbit and into the brain almost to the back of the head. A somewhat similar accident took place in Dublin some twenty years since, when a medical student named Myles was killed by the thrust of an umbrella, the point of which pierced the eyelid and penetrated the brain.

The Annual Report of the President of the Queen's College, Belfast, shows that the aggregate number of students in attendance in the several faculties during the past session was much greater than in previous ones. There were in Arts 177, Medicine 364, Law 23, and Engineering 11, or a total of 575, as against 515 in the session of 1880-81. Hitherto a knowledge of Greek was rigidly enforced in the Matriculation Examination, but now as it is desirable to admit matriculated students of the Royal University *ad eundem*, and as that University allows a modern language to be taken as an alternative for Greek, the College has been compelled to adopt the same course.

The Senate of the Royal University elected five professors of the College to Fellowships, and also nominated three of the medical professors to the important office of examiners in the University. These appointments are of advantage not alone to the College honoured, but further to the general interests of education. The deficiency of accommodation in the College buildings has been more severely felt during the past session than in previous years, owing in part to the great increase in the number of students, and in part to the urgent demand for practical instruction in chemistry, natural philosophy, physiology, and histology. The deficiency has

become so urgent, that unless new buildings and laboratories are immediately provided the progress of the College will be seriously checked and its efficiency endangered. During the present session a beautiful series of microscopical preparations, showing in an admirable manner the whole texture of many organs of the body, was presented by Dr. Thiersch of Leipzig to Dr. Redfern, Professor of Anatomy, who has placed them in the Anatomical Museum.

The death is reported of Dr. W. Nassau Irwin, J.P., of Tirkeenan, county Monaghan, aged seventy-six.

Joseph Byrne, M.D., has been placed on the commission of the peace for the county of Londonderry.

## PARIS.

(From our Paris Correspondent.)

THAT there is an undercurrent in favour of the revival of bloodletting in the treatment of disease is evident from its having been so frequently referred to lately in the Continental and British Medical journals. The question had been raised at the last meeting of the British Medical Association, and it has been lately referred to in THE LANCET, and if I revert to it here it is to give your readers the benefit of the opinions of two eminent physicians of Paris. Marshall Hall, Sir Thomas Watson, and Hughes Bennett, on the English side of the Channel, and Professor Trousseau and others on this side, had by their writings and practice contributed in a great measure to the almost entire suppression of this remedial agent, and by a singular contradiction Professor Peter, who was one of Trousseau's most fervent disciples, and present editor of his clinical work, uses it most freely—that is, in the form of venesection, leeching, and cupping. He employs venesection on rather a large scale, particularly in cases of apoplexy and epilepsy, in which Professor Trousseau condemned it altogether. At his clinical meetings and in his lectures at the School of Medicine Professor Peter teaches that, with all deference to his former master, he has found by experience that bloodletting, if judiciously employed, is invaluable in some cases, and apoplexy is just one of those in which it would be found useful. As in the days before the publication of Professor Trousseau's clinical works, Professor Peter practises bloodletting at the moment of the attack, with the hope of cutting it short, and he does so at a later stage with the view of facilitating the reabsorption of the clot of blood formed at the seat of the lesion, and to moderate the congestion in its neighbourhood. On the strength of this theory, Professor Peter, at his Clinic, lately bled a patient who was upwards of sixty for an attack of apoplexy and hemiplegia of the left side, by which he declared, at a meeting of the Medical Society, that this bleeding had been the means of saving the patient from imminent death. He employs general depletion even in the convulsions following apoplexy, with great benefit to the patient, as he had noticed that, notwithstanding the presence of a large quantity of albumen in the urine, the convulsions and the albumen had entirely disappeared after a small bleeding from the arm. Professor Vulpian employs bloodletting in its various forms in all cases of inflammation, and he has found it invaluable in peritonitis, whether from puerperal or other causes. At the Clinique d'Accouchement, Professor Depaul scarcely employs anything else in puerperal convulsions. He bleeds the patients largely and repeatedly until the most urgent symptoms are relieved, and he has frequently stated at the Academy of Medicine and at other medical societies that the results of the practice that he has carried out for more than a quarter of a century can bear comparison with any other method of treatment adopted by other physicians in similar cases: in fact, the mortality among his patients has always been considerably less.

M. Dumas, the eminent chemist, has been trying some experiments with a concentrated solution of alum, the results of which he lately communicated to the Academy of Sciences. He proposes this substance as an extinguisher of fires, as it renders non-inflammable all substances with which it is placed in contact. He recommends its use for putting out fires in the streets, &c. One of the members present observed that in theory the idea was plausible enough, but that its execution would be simply impractic-

able, owing to the enormous quantities of alum that would be required to meet the demand. It was, however, suggested that several articles in theatres, private houses, shops, &c., might be rendered non-inflammable by having them saturated in a solution of alum, and thus reduce the risk of spreading fires to a minimum.

Those who have been to Paris will recollect the hand balloons started some few years ago by the *Louvre* as a means of advertisement. These, however, have proved somewhat dangerous to the public, several accidents having occurred by the bursting of the balloons. It has been found that they are frequently filled with impure gas, consisting principally of sulphuretted hydrogen, and even arsenic has been found in them. The existence of this danger has been pointed out to the police, and strict measures have been taken to see that the balloons are filled with pure gas.

## NEW YORK.

(From our Correspondent.)

I HAVE noticed several interesting communications in THE LANCET on the subject of "Anæsthetics." Perhaps some notes of recent discussions on this subject in the United States may be welcome.

Dr. J. G. Johnson, in a recent paper before the Medico-Legal Society of New York, in introducing a paper on "Anæsthetics medico-legally considered," referred to the fact that mankind in all ages and in all climes have sought relief from pain. The Egyptians produced sleep by inhalation. Pliny describes a powdered mineral which was applied to wounds to destroy pain; and the power of the mandragora wine used by the ancients was said to be sufficiently potent to render the patient insensible to even the pain caused by amputations. Dr. Johnson gives credit to Morton of Boston, Mass., as the benefactor of mankind, who first made use of an anæsthetic in surgical operations. This was in 1846, just one year before Dr. Simpson discovered the anæsthetic power of chloroform at Edinburgh. He then mentioned Austin's exhaustive experiments, carrying chloroform narcosis even to death, when it was demonstrated that the ano-genital region was the last to give up its sensitiveness. This accounts for the fact that, next to deaths in the dentist's chair, the frequency of deaths during operations for piles and other operations of the rectum has been noticed. Certain portions of the skin and subcutaneous tissue also retain their sensibility with extraordinary tenacity, these being the matrix of the big toe-nail, the margin of the anus, and the whole of the skin of the organs of generation. Dr. Johnson then briefly stated that, with these facts demonstrated, the explanation of those grave charges made by females of respectability became easily enough understood. Those parts conveying sensation after all other parts have had the sensibility overpowered, the pressure of her clothing against the parts stimulating them as she is struggling under the influence of chloroform, and her being held, naturally convey to her the idea of something wrong, not knowing beforehand that the effect of chloroform will make her resist, and that she may forcibly be held down. As to the possibility of administering chloroform to persons while asleep, the question was raised at a recent trial for murder, when a woman, who was found by the side of her murdered husband, claimed that she had been "chloroformed" during her sleep. At the trial Dr. Quimby was called as a witness, and stated that he had tried the experiment, and had been successful in the case of one man and two boys, one of whom was ten and the other twelve years of age. It took about seven minutes to chloroform the man. Dr. Johnson states that the experiment has since been repeated, and that it has been found that with children it can be done by a skilful hand after a little practice, but with adults it is a matter of great difficulty, and unless the person using the chloroform is an expert it is an utter impossibility. The same rules for the use of nitrous oxide should be followed as employed with chloroform—namely, a reclining posture and loose dress. It also stimulates the sexual functions of both sexes; and the precaution should be observed to have a third party present. The following medico-legal points were made:—

1. Anæsthetics do stimulate the sexual functions. Charges made by females under the influence of anæsthetics should be received as the testimony of an insane person; it cannot be rejected, but the *corpus delicti aliunde* rule should be insisted on. 2. Death from administration of chloroform after a felonious assault, unless the wounding was an inevitably fatal one, reduces the crime from murder to a felonious assault. 3. The surgeon has no right to use chloroform to detect crime against the will of the criminal. 4. Gross violations of the well-known rules of administering anæsthetics, life being lost thereby, will subject the violator to a trial on a charge of manslaughter. 5. A surgeon allowing an untrained medical student to administer anæsthetics, and life being therefore lost, will subject the surgeon himself to a suit for damages. 6. The physician who administers an anæsthetic should attend to that part of the work and nothing else; he should have carefully examined the heart and lungs beforehand; he should have the patient in a reclining position, with clothes loose, so as not to interfere with respiration; should have his rat-tooth forceps, nitrite of amyl, and ammonia, and know their uses and when to use them, and artificial respiration. 7. In operations on the ano-genital region, and the evulsion of the toe nail, complete loss of sensation in these parts should never be allowed, and no operation on these parts at all should be performed, under an anæsthetic, unless by approval of a full consultation.

In the discussion which followed Drs. Fennell and Girdner both gave as the result of their experiments that it was next to impossible to chloroform persons in their sleep, as they always found such persons awoke with a slight cough and indications of alarm.—Dr. W. J. Morton spoke of the safety of ether as against chloroform, and considered the choice of an anæsthetic as the most important medico-legal point after all. He said that with chloroform it was always a "toss up" with death, and that it was not carelessness of administration that kills—it was chloroform. True, chloroform had the advantage in agreeableness and amount. As to rapidity there was little difference. Chloroform, according to statistics—and we all know how many deaths are not recorded—is stated to be eight times more dangerous than ether. Richardson placed death from chloroform at 1 in 2500; Andrews, that from ether at 1 in 43,000. Chloroformists were blind to the weight of scientific evidence against this agent. France had used ether from the beginning, and he was glad to find that in England it was coming more into use. Dr. H. McNaughton's report showed that ether was used in a greater number of hospitals than chloroform.—Drs. Bermingham and Miller both spoke of the danger of chloroform, and gave evidence of its fatal effects in their experience of its use.—Dr. Sayre the younger objected to the general denunciation of chloroform, and appeared alone in that opinion. He did not think it was dangerous; on the contrary, he thought it was safer than ether. In his experience with chloroform he had never seen a death from it.—In reply to this, Dr. Morton inquired if it was not an extraordinary argument that each chloroformist must "kill his man," so to speak, before being willing to see any danger in his preferred anæsthetic. According to such a view the experience of others and the science of the times had no value.—Dr. Johnson, in closing the argument, said that the whole question as to which anæsthetic should be used was settled by the fact that chloroform kills without warning; ether does not: therefore the physician is criminally responsible who uses chloroform. He considered that a physician who pursues a course of treatment which is no longer orthodox is in the same position as one who meditates a homicide. That was the law in the United States on this point.

Aug. 11th, 1882.

PARIS ACCLIMATISATION SOCIETY.—Among the medals and prizes awarded by the Acclimatisation Society of Paris at its annual meeting were a gold medal to Sir James R. G. Maitland of Sauchie, near Stirling, for his establishment of fish culture; a silver medal to Mr. James E. Harting, for his work on "Ostrich Farming and Historical Researches on the Extinct Animals of Great Britain"; a silver medal to Mr. Harvie Brown, for his work on "The Reintroduction of the Capercaille into Scotland"; and a sum of 300 francs to Mr. Alfred Wailly of the Clapham-road, for his successful labours in breeding and crossing exotic silkworms.

## Obituary.

### DR. CHARLES MOREHEAD, C.E.I.

THIS distinguished member of the medical service of India died at Wilton Castle, Redcar, Yorkshire, on Aug. 24th, in the seventy-fifth year of his age. Dr. Morehead was the youngest son of the late Reverend Robert Morehead, D.D., Rector of Easington, Yorkshire, who for many years before had been the incumbent of one of the largest episcopal churches in Edinburgh, where the subject of this notice was born and educated. Charles Morehead was from boyhood an earnest student. After receiving an excellent general education, he began his medical studies in the University of Edinburgh, where he soon distinguished himself in every branch of science. From an early period of his career he attracted the attention of Professor Alison by his zeal in the prosecution of clinical medicine, and to the end of his university career was a favourite pupil of that much-loved physician, whose clinical clerk he became. Having taken his degree, Dr. Morehead proceeded to Paris, and for more than a year pursued his clinical studies under Louis, keeping up intimate intercourse with that great physician until his death. In 1829, he entered the Bombay Medical Service, and after the usual probationary course served on the personal staff of Sir Robert Grant, Governor of Bombay. From an early part of his career Dr. Morehead was a contributor to the *Transactions of the Medical and Physical Society of Bombay*, of which he became President in 1837, a position he retained until the year 1859. On the death of Sir Robert Grant, in 1838, Dr. Morehead was appointed to the European and Native General Hospitals of Bombay, and in 1845 became the first principal in the Grant Medical College, and Professor of Medicine in that institution. On the establishment of the Board of Native Education in 1840, he was appointed secretary to the Board, an office he held for five years. Dr. Morehead continued to hold his position as principal of the Grant Medical College and physician to the Jamsjee Jejeebhoy Hospital until 1859, when he returned to Europe, and finally retired from the service in June, 1862. He was appointed honorary surgeon to the Queen in 1861, and, somewhat late in the day, his eminent services to the State were recognised by his being created a Companion of the Indian Empire. The work by which Dr. Morehead was best known in Europe was his "Researches on the Diseases of India," a work of rare merit, built on the sure foundation of careful clinical experience. From his youth upwards he was a painstaking case-taker. Trained, as we have seen, in clinical studies by such great diagnostic physicians as Alison and Louis, he was *facile princeps* in this difficult part of the physician's art, and not in tropical diseases only, but also in cardiac and pulmonary affections; he could always in this particular hold his own in consultation with physicians in any part of the world. As a teacher Dr. Morehead will long be remembered in the school he may be said to have founded in Bombay. In the hospitals fortunate enough to have had him as leading physician, the diagnostic faculty of which we have spoken had an ample field for its exercise, of which his pupils had the benefit; to their service he gave his time, his great abilities, and his vast experience without stint or measure, and we cannot wonder that the native and Eurasian community of Bombay, to whose service he devoted his life, held him in high esteem, and will, now that he rests from his labours, cherish his memory as that of a friend to the best interests of their respective races. Whatever may be the future of the Medical Service of India, it has a past of which its surviving members may well be proud. In the long list of those who in India did honour to our profession, there are few names more deserving of fame than that of Charles Morehead.

### THE SCARLET FEVER EPIDEMIC AT ACCRINGTON.—

This outbreak is assuming still more alarming proportions. This week between thirty and forty new cases have been reported to the local authority, and there have been four more deaths, making about forty fatal cases since the beginning of August. The fever has extended to Oswaldtwistle, where several cases are reported to have occurred.

## Medical News.

**BRITISH MEDICAL SERVICE.**—The following is a list of the candidates who were successful for appointments as Surgeons in this Service at the competitive examination in London, on Aug. 21st:—

Marks.	Marks.
Macpherson, W. G. .... 2365	Stuart, J. R. .... 2015
Simpson, R. J. S. .... 2305	Morse, T. R. .... 1975
Reld, F. W. .... 2233	Deeble, W. B. C. .... 1960
Phippa, E. V. A. .... 2180	Prendergast, J. M. .... 1935
Hunter, V. E. .... 2160	Bond, R. P. .... 1905
Baird, A. .... 2155	Stewart, J. McD. .... 1890
Hamilton, T. W. O'H. .... 2065	Thomas, G. T. H. .... 1870
Semple, D. .... 2030	

**INDIAN MEDICAL SERVICE.**—The following is a list of the candidates for Her Majesty's Indian Medical Service who were successful at the competitive examination held at Burlington-house, on Aug. 21st and following days. Thirty-nine candidates competed for eight appointments. All were reported qualified:—

Marks.	Marks.
Leahy, A. W. D. .... 2960	Davis, R. E. S. .... 2840
Webb, W. W. .... 2530	Fuller, H. K. .... 2320
Weir, R. R. .... 2510	Nelson, W. H. .... 2220
Burke, W. H. .... 2377	Crimmin, John .... 2185

**NAVAL MEDICAL SERVICE.**—The following is a list of the successful candidates for appointments as Surgeons in the Royal Navy at the competitive examination at Burlington-house on Aug. 21st and following days. Eight other candidates were reported by the examiners as qualified:—

Marks.	Marks.
Logan, J. S. .... 2090	Martin, J. M'C. .... 1850
Lawson, R. J. .... 2030	Bagnall-Oakeley, J. L. .... 1770
Cashin, J. .... 2025	Woores, F. .... 1755
Nunan, T. .... 1980	Craig, W. M. .... 1740
Norman, W. H. .... 1970	Jackson, H. S. .... 1700
Todd, P. E. .... 1950	Phillips, J. M. .... 1695

**APOTHECARIES' HALL.**—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on Aug. 31st:—

Batt, Richard Bush Drury, Camden-road.  
Kirk, Thomas Deck, Creavory, Antrim, Ireland.  
Serres, John James, Colchester House, Ankerly.  
Whitcombe, Philip Percival, Gravesend.

The following gentleman also on the same day passed the Primary Professional Examination:—

Llewellyn, James Davies, London Hospital.

The following gentlemen passed and received certificates to practise, on Sept. 7th:—

Church, William, Hereford-road, Bayswater; Hull, Walter, Acton, Middlesex; Larder, Herbert, Denmark-hill, Wimbledon.

The following gentlemen also on the same day passed the Primary Professional Examination:—

Bullock, Thomas Warren, St. Thomas's Hospital; Jefferies, Horace, Queen's College, Birmingham; Plummer, Henry Geo., Guy's Hospital; Mander, Percy Robert, Westminster Hospital.

The late Dr. John Boyd Baxter, for many years Procurator Fiscal in Dundee, has bequeathed the sum of £10,000 to the College in Dundee, and £1000 to the Royal Infirmary.

The population of Iceland, which has already suffered severely from famine, is being decimated by an epidemic of measles.

The alleged pollution of the river Derwent at Buxton is about to be made the subject of a public inquiry by the conservators of the Trent.

MR. CHRISTOPHER COOKE, late of 51, Lincoln's-inn-fields, has bequeathed £10 each to the Cornwall Infirmary, the Hampshire County Hospital, and King's College Hospital.

**TYPHUS FEVER.**—Three Roman Catholic Priests have recently died from typhus fever at, or in the neighbourhood of, Liverpool, within a comparatively short period of each other, having, it is supposed, caught the infection while visiting members of their congregation who were stricken with the disease.

**MEDICAL MAGISTRATE.**—H. S. Gaye, M.D., of Newton Abbot, having resigned the coronership, has been placed on the Commission of the Peace by the Lord Lieutenant of the County.

It is asserted that in consequence of the prevalence of foot-and-mouth disease in Staffordshire, the County Agricultural Society has abandoned its annual show, which was to have been held at Lichfield at the end of the present month.

**PRESENTATION.**—A few members of the Lily of the Vale Lodge, A.O. Free Gardeners, recently waited upon Dr. Cairns at his residence and presented him with a handsome eight-day clock as a mark of esteem on the occasion of his marriage. Dr. Cairns thanked the members for the kindly feeling manifested towards him.

**DIPHTHERIA.**—At Port Washington, Long Island, U.S.A., ten persons in one family are said to have been suffering from diphtheria, which is supposed to have been contracted by drinking from a tin dipper which had been used by a boy in a neighbouring family who had the disease.

At Crediton, typhoid fever has made its appearance with such severity that the authorities have prohibited the reopening of the public schools of the town, and the scholars, on presenting themselves, were ordered to return to their homes.

A LETTER was read at the meeting of the monthly board of the Bucks Infirmary on the 6th inst. from Mr. Ceely, tendering his resignation of the post of surgeon to this institution, which he has held for a period of fifty years. The board expressed in a resolution its deep sense of the valuable services rendered by Mr. Ceely to the infirmary during the past half-century.

THE Aberdeen University Authorities have just received from Mrs. Marr, widow of the late Mr. John Marr, music-seller, of Aberdeen, a gift of £2000 to provide for the foundation of medical bursaries in such department as the Faculty and Senators may advise. This is the first step towards the establishment of medical bursaries in Aberdeen, and the gift has been made in response to a public desire that the bursaries should not be exclusively confined to the Arts and Divinity Faculties.

At a recent meeting of the Liverpool City Council the Health Committee presented a request that they might be empowered to take the necessary steps for procuring a provisional order for amending the Local Sanitary Acts by providing for the notification of infectious diseases. Mr. A. B. Forwood moved the confirmation of the committee's request, and stated they had in contemplation to recommend the compulsory registration of all cases of infectious disease. The Council ultimately agreed to the Health Committee's request.

**ANTI-VACCINATION.**—At the Leicester Borough Police-court, a few days ago, nineteen persons were summoned for refusing to comply with the Compulsory Vaccination Acts by not having their children vaccinated. There are several thousand unvaccinated children in the town, and the number is increasing at a very rapid rate, although there are more prosecutions under these Acts in Leicester alone than in all the other large towns in the kingdom put together. Notwithstanding this state of things, the town is perfectly free from small-pox. Eighteen of the defendants were fined 10s. each or seven days' imprisonment, and the other case was adjourned.

**MEDICAL PRIZES.**—At the recent meeting of the British Medical Association, the Stewart prize, of the value of 50 guineas, founded by Dr. A. P. Stewart, F.R.C.P., was awarded to Dr. Vandyke Carter, M.D. Lond., Surgeon-Major, Indian Medical Department, for his work entitled "Spirillum Fever." At the same meeting the Middlemore prize, of the value of 60 guineas, was awarded to Mr. William Adams Frost, F.R.C.S., Assistant Ophthalmic Surgeon to St. George's Hospital, for his essay on "The Scientific and Practical Value of Implements in Ophthalmic Medicine and Surgery made or published during the past three years."

## Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning at the latest.

**BARROW, ALBERT BOYCE, M.B.Lond., F.R.C.S.Eng.**, has been appointed Assistant-Surgeon to the West London Hospital.

**BIRDWOOD, ROGER ALAN, M.A.Camb., M.R.C.S.**, has been appointed Surgeon to the Wynad Medical Board, Pundalur.

**BUSH, J. PAUL, M.R.C.S., L.S.A.Lond.**, has been elected House-Physician of the Bristol Royal Infirmary, vice Dr. Watson, resigned.

**COBOLD, C. S. W., M.D.**, Assistant Medical Officer at Colney Hatch Asylum, has been appointed Medical Superintendent of Earlswood Asylum, vice Grabham, appointed Commissioner in Lunacy for New Zealand.

**COLLINS, G. H., M.R.C.S.**, has been appointed Resident Medical Officer at the Wednesbury Small-pox Hospital.

**COURTENAY, JOHN HOYSTED, M.K.Q.C.P.I., L.R.C.P.Lond., L.R.C.S.I., L.M.**, has been appointed Honorary Surgeon to the Echuca District Hospital, Echuca, Victoria, Australia.

**CRADDOCK, FREDERICK HURST, B.A.Oxon., M.R.C.S., L.S.A.Lond.**, Senior Assistant Medical Officer and Deputy-Superintendent of the Worcester County and City Asylum, has been appointed Medical Superintendent of the Gloucester County Asylum.

**DOUDNEY, G. H., M.B.**, has been appointed House-Surgeon to the Seamen's Hospital, Ramsgate, and Visiting Surgeon to the Ramsgate and St. Lawrence Dispensary, vice E. W. Farmer, M.R.C.S., resigned.

**GARMAN, JOHN C., L.R.C.P.L., M.R.C.S.**, has been appointed Medical Officer for the Workhouse of the Hackney Union.

**HENDLEY, HAROLD, M.R.C.S.**, has been appointed House-Surgeon to the West London Hospital, vice Rickard W. Lloyd, M.R.C.S., resigned.

**HEY, Mr. GEO.**, has been appointed Vaccination Officer for the Bradford Union.

**HOPKINS, JOHN WALTER, M.R.C.S.**, has been appointed House-Surgeon and Secretary to the Royal Isle of Wight Infirmary, Ryde, vice T. M. Kendall, L.R.C.S.Ed., L.R.C.P.Ed., resigned.

**KENNA, DENIS P., L.R.C.S.I.**, has been appointed Resident Surgeon to St. Vincent's Hospital, Stephen's-green, Dublin; also Visiting Surgeon to St. Vincent's and Mullen's Convalescent Homes, Black-rock, co. Dublin.

**MITCHELL, H., M.D.Ed.**, has been appointed Medical Officer for the First District and Workhouse of the Cokermonth Union.

**MOORE, Mr. E. H.**, has been reappointed Analyst for the Eastern Division of the County of Sussex.

**PENNY, H. J., L.K.Q.C.P.I.**, has been appointed Medical Officer for the Third District of the Barnet Union.

**PROCTOR, SAMUEL FITZGERALD, M.R.C.S., L.R.C.P.Ed.**, has been appointed Assistant Colonial Surgeon to the Colony of St. Lucia, West Indies.

**RAWLE, FRANCIS, M.R.C.S., L.S.A.Lond.**, has been appointed Medical Officer for the Titchfield District of the Fareham Union.

**SIDDALL, GEORGE, M.R.C.S., L.S.A.Lond.**, has been appointed Vaccination Officer for the Cleckheaton District.

**SWABY-SMITH, C., M.R.C.P.Ed., M.R.C.S.**, has been appointed Honorary Surgeon to the West Metropolitan Fire Brigade.

**THOMPSON, C. EMILIUS, M.R.C.S.**, has been appointed Medical Officer to the Yatala Labour Prison, Salisbury, S.A.

**THOMPSON, JAMES, M.D., M.K.Q.C.P., L.R.C.S.I.**, has been elected Surgeon to the Surgical Appliance Society, Finsbury-circus.

**WARREN, WILLIAM, L.R.C.S.I., L.M.K.Q.C.P.I.**, has been elected Honorary Physician to the Alfred Hospital, Melbourne.

**WEST, JOHN A., M.R.C.S., L.S.A.Lond., A.K.C.**, has been appointed Clinical Assistant and Registrar to the North-Eastern Hospital for Children, Hackney-road.

**PENRUDDOCKE**.—On the 5th inst., at Winchcombe, Gloucestershire, the wife of Charles Penruddocke, M.R.C.S., L.R.C.P.Ed., of a son.

**REID**.—On the 5th inst., at 12, Bridge-avenue, Hammesmith, the wife of John Reid, M.D., of a daughter.

**SEMON**.—On the 9th inst., at Welbeck-street, Cavendish-square, W., the wife of Felix Semon, M.D., M.R.C.P., of a son.

**THOM**.—On the 10th inst., the wife of Alex. Thom, jun., M.A., M.D., & C.M., of a son.

**WITHINGTON**.—On the 4th inst., at Rodney-street, Wigan, the wife of Herbert Withington, L.K.Q.C.P.I., of a daughter.

## MARRIAGES.

**CLARKE—JUKES**.—On the 12th inst., at St. Stephen's Hamstead, Fincastle George Barlow Clarke, M.D., second son of Major-General Wm. Calcott Clarke, late Madras Staff Corps, to Kate Blanche D'Almeida, second daughter of Miles Prendergast Jukes, Esq., of Belaise-park, N.W.

**CLOUGH—CREE**.—On the 7th inst., at St. John's Church, N., Morley, Edision Clough, of Hambledon, Hants, to Annette Cree, only daughter of Edward H. Cree, Esq., M.D., Deputy Inspector-General of Hospitals and Fleets (retired).

**FLANAGAN—HILL**.—On the 26th July, at the Pro-Cathedral, Georgetown, Demerara, H. E. B. Flanagan, Army Medical Department, only son of Lieut.-Colonel J. B. Flanagan (late 81st Regt.) to Marian Emily, only daughter of the late James Hill, Esq., of Demerara.

**HALLETT—PRICE**.—On the 6th inst., at the Parish Church, Kimbolton, Henry Arthur Hallett, M.D., son of the late Colonel Hallett, C.B., to Mabel, third daughter of the Rev. E. H. Price.

**HOWE—LE FEAX**.—On the 30th ult., at the Parish Church, Llanidloes, Jonas Howe, L.R.C.S.E., of Castle House, Llanidloes, to Emma Elizabeth (Emmie), youngest daughter of William Le Feaux, Esq., of Penrallt House.

**LIEBSTEIN—FLETCHER**.—On the 2nd inst., at the Congregational Church, Bournemouth, Hermann Liebstein, M.D., of Drayton-park, London, to Jeanne, younger daughter of the late Rev. Joseph Fletcher, of Christchurch, Hants.

**MACCULLOCH—ROBERTS**.—On the 29th ult., at the Church of St. John the Baptist, Islington, S. H. Macculloch, M.B.Ed., C.M., of Sydney, N.S.W., to Jane, daughter of Edward Roberts, Esq., of Downham-road, N.

**MOLINEUX—FINCHER**.—On the 2nd inst., at Hastings, Sussex, Edward Molineux, M.R.C.S., L.R.C.P., son of Geo. James Knapp, of Clifton, to Isabella Rosalind, eldest daughter of the late Rev. J. Guillemard Fincher, Rector of St. Alban's, Manchester.

**MURRAY—MACKAY**.—On the 30th ult., at the Cathedral, Inverness, R. D. Murray, M.B., Surgeon H.M. Bengal Army, to Mary M'Innes, eldest surviving daughter of Deputy-Surgeon-General Mackay, M.D., Indian Army.

**PAYNE—MACPHERSON**.—On the 2nd inst., at St. Mary Abbott's, Kensington, Joseph Frank Payne, M.D., Fellow of Magdalen College, Oxford, and Assistant-Physician to St. Thomas's Hospital, to Helen Curtis, eldest daughter of John A. Macpherson, of Umina, Toorak, Melbourne, and Pembroke-crescent, Bayswater.

**PEIRCE—FEARNLEY**.—On the 5th inst., at Christ Church, Moreton, by the father of the bride, Francis Peirce, M.D., Hoylake, Cheshire, son of John Peirce, M.D., F.R.C.S.I., late of Newcastle West, Limerick, to Rosa, second daughter of the Rev. M. Fearnley, Rector of the Parish.

**PENDAVIS—GODEFROY**.—On the Feb. 9th, at San Pablo, Iquique, S.A., William Frederick Pendavis, L.R.C.P.Ed., M.R.C.S.Eng., &c., son of the late Rector of St. Peter's Manchester, to Luisa, daughter of the late Mons. Emile Godefroy, of Bordeaux, France, and Lima, S.A.

**PERRY—DONALDSON**.—On the 5th inst., at St. Saviour's Church, Bath, Deputy Surgeon-General W. Perry, late Royal Artillery, to Adeline Louisa, third daughter of the late Rev. J. W. Donaldson, D.D.

**PILLEAU—JOHNSTONE**.—On the 5th inst., at St. George's, Hanover-square, Henry Pilleau, Deputy Inspector-General of Hospitals, to Mary, widow of H. E. Johnstone, late of Broncroft, Salop.

**ROWE—WHEELHOUSE**.—On the 7th inst., at the Parish Church, Leeds, by the Rev. John Gott, D.D., the Vicar, George Herbert Rowe, M.R.C.S., to Caroline Agnes, eldest daughter of C. G. Wheelhouse, F.R.C.S., of Hilary-place, Leeds.

**SOUTHAM—HUGHES**.—On the 7th inst., at the Parish Church, Staverton, S. Devon, Frederic Armitage Southam, F.R.C.S., of Pendleton, Manchester, to Amy Florence, daughter of the Rev. J. B. Hughes.

**STEWART—BREMNER**.—On the 5th inst., at the Manse, Portsoy, William Lemmon Stewart, M.A., M.D., of Portsoy, to Jessie Anne, eldest daughter of the late Alexander Bremner, Esq.

**WILSON—WARD**.—On the 29th ult., at St. Luke's, Maidenhead, Joseph Wilson, M.D., 42nd A.L.I., to F. Gertrude, daughter of R. A. Ward, Esq.

## DEATHS.

**BADDELEY**.—On the 8th inst., at Gnosall, Staffordshire, George Augustus Baddeley, M.R.C.S., aged 58.

**GROSS**.—On the 5th inst., at St. Saviour's Infirmary, Westmoreland-road, Walworth, S.E., Constance, infant daughter of Charles Gross, L.R.C.P.Lond. &c., Medical Superintendent.

**HAWARD**.—On the 28th ult., at Little Blakenham, Ipswich, Deputy Surgeon-General Wallace Haward, aged 51.

**PITMAN**.—On the 1st inst., at his residence, Wyborne, Cheltenham, Henry Pitman, Deputy Inspector-General of Hospitals, Indian Army, retired, eldest son of the late Captain Pitman, of H.M.'s 59th Regiment, aged 64.

**RAYNER**.—On the 8th inst., at New Hall, Birstal, near Leeds, Robert Rayner, M.R.C.S.E. & L.S.A.Lond., aged 57.

**REDWOOD**.—On the 30th ult., at the Lawn, Rhymney, Monmouthshire, Lewis Redwood, M.R.C.S., L.S.A.Lond., for 45 years Chief Surgeon of the Rhymney Iron Works, aged 73.

**STUMMER**.—On the 4th inst., at Craiglands, Ilkley, Yorkshire, Dr. Leopold Stummer, aged 73.

**N.B.**—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Births, Marriages, and Deaths.

### BIRTHS.

**BARR**.—On the 6th inst., at St. Domingo-grove, Everton, the wife of James Barr, M.D., of a son.

**BEAMAN**.—On the 1st inst., at Bedford, the wife of Brigade-Surgeon A. H. Beaman, of a daughter.

**DINGLE**.—On the 4th inst., at 61, Bunhill-row, Finsbury, the wife of William Alfred Dingle, L.R.C.P.Lond., M.R.C.S.Eng., L.S.A.Lond., of a daughter.

**EDWARDES**.—On the 5th inst., at Stanley House, Bath-road, Hounslow, the wife of W. Whitfield Edwardes, M.D., of a son.

**JACKSON**.—On the 12th inst., at Lansdowne House, Tottenham, the wife of G. H. Jackson, jun., Esq., Surgeon, of a son.

**KESTEVEN**.—On the 6th inst., at Holloway-road, N., the wife of W. H. Kesteven, M.R.C.S., of a son.

**MEARNS**.—On the 1st ult., at Prince Albert, Cape of Good Hope, the wife of J. Herbert Mearns, M.D., J.P., of a daughter.

**NICHOLSON**.—On the 6th inst., at Benalla, S.A., the wife of John Nicholson, M.D., of a son.

**OSWALD**.—On the 1st inst., at 43, Clapham-road, S.W., the wife of Robert J. W. Oswald, L.R.C.P.Ed., L.R.C.S.Ed., M.R.C.S.E., &c., of a daughter.

**PARSONS-SMITH**.—On the 30th ult., at Park-Hyatt, Addiscombe-road, Croydon, the wife of Dr. Parsons-Smith, of a son.

## Notes, Short Comments, and Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*We cannot prescribe, or recommend practitioners.*

*Local papers containing reports or news-paragraphs should be marked.*

*All communications relating to the editorial business of the journal must be addressed "To the Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

### "THE STUDENTS' NUMBER."

We have received several communications from the authorities of hospitals omitted from the Students' Number of THE LANCET. We endeavoured as far as possible to insert all hospitals associated with medical schools or having educational classes. Hospitals possessing neither of these qualifications were in many instances unavoidably omitted. Respecting the mistakes referred to, we have to state that the lists were prepared from "copy" officially supplied.

*F.R.C.S. Edin.*—There is no examination for this title. Next to holding a diploma from one of several corporations, the principal condition of fitness is that the candidate shall be able to pay £25 "to the college funds." Attempts are, we know, made to palm off "F.R.C.S. Ed." as equivalent to and equally honourable as "F.R.C.S. Eng.," but these attempts, it is needless to say, are dishonest.

*A Beginner* will find the information he asks for in the Address to Students, contained in our last issue.

### URTICARIA AND MOSQUITO-BITES.

*To the Editor of THE LANCET.*

SIR,—In your issue of August 19th, "L.R.C.P." asks for a suggestion as to the treatment of a case of urticaria. My experience of the subject being small, I feel the greatest diffidence in venturing upon an opinion, and only do so because no response has hitherto been forthcoming from more competent authorities. I read recently in a medical paper that Dr. Schwimmer treats urticaria by the internal administration of atropine. I cannot say that I have had the opportunity of verifying the efficacy of the remedy in the ordinary form of the affection, but I can testify to its value in the variety produced by the bites of gnats and mosquitoes.

The past summer, notwithstanding the moderate degree of heat, has been remarkable in Paris for the number of these insects, and I for one have been severely visited by them. In my case each bite gives rise in the course of a few minutes to a raised white lump, which disappears after a variable time, leaving an irritable papule, lasting for some days. I find that the application of a solution of atropine shortens the whole process, and instantly relieves the itching. The solution I have used is one part in a thousand.

"L.R.C.P." does not say what are the remedies he has employed. I take it that, with the exception of the sluggishness of the liver, all other likely sources of reflex irritation have been eliminated. Whether there be any gastro-intestinal disturbance or not, this condition of the liver might be benefited by a course of rhubarb and quinine. If all means of removing and allaying irritation fail, there still remains the possibility of inhibiting the morbid reflex by bromide of potassium; and if it comes to this, it would be well to associate it with arsenious acid.

I am, Sir, yours faithfully,

Paris, August 31st, 1882. OSCAR JENNINGS, M.D.

*To the Editor of THE LANCET.*

SIR,—Having met with a number of cases similar to the one described by "L.R.C.P." in your issue of August 19th, I should recommend him to try mercurial treatment, which has proved the most successful in my hands. For a child four years old I would advise one grain of mercury with chalk, to be given three times a day, combined with the same quantity of compound cinnamon powder in order to prevent griping. One week of this treatment has generally sufficed in my hands to subdue the more severe symptoms, and I have then allowed the eruption to take its own course, which has usually been to die away gradually. Acetate of lead ointment may be used externally to relieve the itching, and an aperient of tartrate of soda (say, thirty or forty grains in his case) may be given in the morning before breakfast once or twice a week. Many of the cases are, I believe, syphilitic.

I remain, Sir, yours obediently,

Oldham, August 29th, 1882. ANACHARIS.

### HABITUAL DRUNKARDS.

*M.D.*, writing to the *Standard*, makes the following suggestion:—"There is one way of dealing with habitual drunkards which has not yet been noticed—that is, to send them for a voyage in a teetotal ship. If a 'retreat' could be established on a small island—say one of the Channel or Scilly Isles—there would be no difficulty from neighbouring public-houses, and no necessity to send a guide with the patient when he goes out."

*Dr. Campbell Black* (Glasgow).—The blocks have been received.

*Mr. Wm. Anderson* (Welbeck-street).—The article will appear next week if possible.

*Mr. H. Kesteven* (Holloway-road).—We may probably notice the production enclosed in our correspondent's note.

### "DIGITATED SOCKS."

*To the Editor of THE LANCET.*

SIR,—I was glad to find in a recent number of THE LANCET a notice of the above, which appear to be very little used at home, as they are almost unknown abroad. After wearing them constantly for many years, I have formed a very high appreciation of their value, especially in the tropics, where the trifling additional expense and trouble which their use involves are much more than compensated for by the cleanliness and comfort which are thereby insured. Whilst the barbarous and cruel custom which prevails in China of contracting the female foot finds imitators among a large portion of the British public, and deformity, with a halting gait, is vainly supposed to secure more admirers than natural ease and grace of deportment, these invaluable foot coverings will of necessity be disregarded, because the breadth of the shoe or boot must contain ten thicknesses instead of two of silk, thread, or other material. Except in the naval and military services, boots and shoes are, as a rule, made too narrow. Too little pains are bestowed upon the fitting of children's feet, and the injury resulting from compression of the toes in infancy and childhood can never be repaired. The veterinary surgeon gives much attention to the shoeing of horses, whilst the family doctor pays little or no regard to the children's feet or shoes. They have to put on the number which is nearest to their size, when perhaps the whole thing is a misfit; whereas a farrier will rarely, if ever, put a shoe upon a horse without heating and shaping it a little. The importance of being "kind to our old age" is well illustrated in the treatment of the feet. All the adages about "poor feet," "treading on corns," "as easy as an old shoe," &c., doubtless have their rise in the needless suffering which is inflicted by parents upon children, and by ignorant and foolish people on themselves. Why should not a new shoe be just as comfortable as the old one? Most certainly it ought to be, and more so. Let us abandon the silly and most injurious high heel, add to the breadth of the sole, let the toes be entirely free from pressure or restraint, use digitated socks, bind the shoe firmly upon the instep, and so soon as the necessity for an unnatural covering ceases, put off the leather shoes, and habitually wear indoors something lighter and more pervious to the moisture of the skin. As much as possible let children run about in the house without any covering on their feet at all, putting them on and off at the threshold like the Japanese. Their straw sandals, without any socks, are admirably adapted for indoor use, and a beginning might very well be made with the young people. These sandals, when lined with cloth or leather, are also an invaluable accompaniment of the digitated socks.

The human foot in England has been so long neglected and concealed in dark, dismal recesses, never seeing the air and light, that its persistent maltreatment has resulted in deformity and degradation. Why should it not receive the same consideration as the hand? We are so accustomed to view the foot, as a whole, encased in its often ill-chosen covering of patent leather, that to display it in its natural form would be deemed an impropriety, as the growth of hair upon the face was considered in England twenty-five years ago. In due time, however, common sense must prevail over ignorance and prejudice.

I am, Sir, yours faithfully,

Hong Kong, July 12th, 1882.

W. J.

*Inquirers* should apply at the Admiralty, Whitehall, for the requisite information.

*H. C. J.*—We cannot oblige our correspondent.

*Mr. E. N. Edmunds.*—The subject shall not be lost sight of.

*Mr. J. W. Stedman* (Godalming).—Next week.

### NORTH-WEST LONDON HOSPITAL.

*To the Editor of THE LANCET.*

SIR,—In your issue of Sept. 2nd it is stated that the committee of this hospital are in treaty for the purchase of two houses in Bell-street, Edgware-road, for a children's hospital. I beg to state that my committee have no intention of giving up the houses they now hold in the Kentish-town-road, where twenty-six beds are provided. On the contrary, they are about to build a large waiting-room and additional consulting-rooms, &c., on these premises. Will you kindly give this correction in your next number?

I remain, Sir, your obedient servant,

ALFRED CRASKE, Sec.

North-West London Hospital, Kentish-town-road, N.W.,  
Sept. 5th, 1882.

**Mr. H. C. Moore (Hereford).**—In THE LANCET of the 26th ult., at page 337, will be found a letter on the subject containing the address, and offering assistance to any medical man desirous of experimenting.

**Mr. R. W. Western.**—Certainly not.

### "BICYCLE AND TRICYCLE RIDING."

To the Editor of THE LANCET.

SIR,—I have watched with considerable interest the letters which have appeared from time to time on the above subject, and as I differ in opinion partly from those gentlemen, I should feel obliged if you will insert the following. I have had considerable experience both as a rider and also of observing others who make use of the bicycle, both as means of exercise and in the capacity of racing. I also hold the post of honorary surgeon to one of the largest clubs out of London. Numbers of bicyclists in my own club and also in neighbouring clubs have consulted me as to their chance of becoming affected either with hernia or varicose veins. I have always been very careful in giving my opinion.

1st. Those who already have a hernia should be extremely careful in not fatiguing themselves, as I find that during the taking of undue exercise—as, for instance, racing or hill-climbing—on the machine, the tendency is to the coming down of the rupture. I have seen a case of this where a competitor had to be lifted off his machine. I returned the hernia without any difficulty, but he was violently sick. Also a truss should constantly be worn, as a well-fitting truss can be kept in position without any difficulty.

2nd. Those who are likely to be affected with hernia should observe the above precautions (with the exception of the wearing of a truss, which is unnecessary), as there is a distinct predisposition in some persons.

3rd. As to bicyclists and tricyclists suffering from varicose veins, they are few and far between, and the malady is seldom caused by the use of either the bi or tri order. It is most noticeable in those who do any large amount of running or walking, and in this fact there are numerous instances, more or less severe.

There is also another disease which is not mentioned by any of your correspondents—e.g., varicocoele. I have known this brought on or aggravated in a few instances by long distances, constantly repeated, on either machines or in walking. This disease is far more common than is at present anticipated; still, I do not mean to say that it is caused by the use of the bicycle only where undue exercise is taken for great distances; but when present it is certainly made much worse if the person so affected takes an undue amount of exercise, but not so under any moderate amount.

As to whether the bicycle or tricycle is most likely to cause rupture, or, if present, aggravate it, I should think that the tricycle is the most likely, owing to its more open structure as compared with the bicycle, and also to the different action required by the muscles. But, taking the exercise as a whole, in moderation it is perfectly safe, and the good derived from it speaks for itself when we look at a collection of bicyclists making their way along the country roads, looking, without exception, as jolly and in as perfect health as anyone could wish to be; and in truth they are, on the average, the healthiest set of athletes in existence.

I am, Sir, yours very truly,

CHARLES WM. ROBINSON, M.R.C.S. Eng., &c.

North Shields, Sept. 6th, 1882.

To the Editor of THE LANCET.

SIR,—Mr. Westropp is quite right in supposing that his racing friends are suffering from varicose veins through bicycle-riding. In fast riding it necessarily follows that the veins of the lower extremity are filled faster than the saphena can empty them, and as racing men are of necessity much on the track even when not actually competing, it follows that a permanent over-distension of the veins ensues, which will often in these cases be found well marked as far up as the saphenous opening itself. Such a condition may of course happen to men of weak fibre who only ride moderately, and is naturally incidental to tricycle riders as well as bicyclists.

With reference to the statement that Mr. Westropp knows some persons suffering from hernia who dispense with their trusses when riding tricycles, it is only necessary to suggest that if he is their surgical adviser, he should inform them of the urgent need of their trusses being worn at all times except when lying down, since even tricycle-riding can hardly be a good alternative for truss wearing.

I am, Sir, your obedient servant,

W. G. CRESWELL, L.R.C.P. Edin.

Birmingham, Sept. 3rd, 1882.

To the Editor of THE LANCET.

SIR,—Whilst on the subject of bicycle riding, it may be interesting to some of your readers to be informed of a peculiarity which occurred to me some years ago, when practising on the then newly invented machine. It was this. When I became tolerably expert at the exercise, I invariably noticed, after being at it for about twenty minutes, that my left thigh swelled enormously—so much so that my trousers were distended to the utmost, without my feeling any pain whatever. I thought it prudent, however, to discontinue the recreation, which I was very fond of, and so cannot say whether a similar result would happen with the improved bicycle now in use. I may add that I am a fair athlete, a good pedestrian, and I ride a great deal; but in none of these pursuits have I experienced even a tendency to the discomfort above mentioned.

I am, Sir, yours truly,

M.R.C.S.

Southsea, Sept. 13th, 1882.

### EXTRAORDINARY SURGICAL OPERATION AT ENNISKILLEN.

NEWSPAPER accounts of surgical operations, especially when full of details, imply a very great responsibility of the operator. Either he or some injudicious friend, whom he should disclaim with decision, must supply particulars. The professional feeling against such reports in lay papers is very strong.

**Bibliophile.**—The Library of the Royal College of Surgeons contains about 40,000 volumes, as also the Young collection of medical portraits, and some of those collected by Mr. William Wadd, a former member of the Council of the College; the remainder were obtained by the Royal Medical and Chirurgical Society, and Mr. T. M. Stone, of the College of Surgeons.

**H. F. P.**—We cannot discuss such absurdities.

### "SUCCESSFUL PRECAUTIONARY MEASURES AGAINST PUERPERAL FEVER."

To the Editor of THE LANCET.

SIR,—In your issue of August 19th, a letter appeared under the above heading in which the writer describes having used various antiseptic measures with a view of preventing the occurrence of puerperal fever in a woman who was delivered in the same room where there was a child suffering from scarlet fever; and apparently he is in doubt as to whether the non-occurrence of the disease was due to the measures adopted or not.

In order to show him that as favourable a result may follow without using any precautions whatever, I may mention that in December last year I attended a Mrs. N—, who was delivered of her eighth child; on coming downstairs from the bedroom I was asked to see Mrs. N—'s seventh child, who was suffering from a severe attack of scarlet fever, the rash being fully developed, with sore-throat, and a temperature in the axilla of 104°. Before leaving the house I gave special directions that on no account should the child be taken upstairs, that she should be kept in a separate room downstairs, and that the monthly nurse in attendance on Mrs. N— should not be permitted to enter the room in which the child was to have been placed. I say was to have been placed because my directions were entirely ignored, so much so that on my visit to my patient on the following day, not only was my scarlet fever patient in the same room, but to my great surprise was in the same bed with her mother, and continued so until the latter came downstairs five days after delivery; the excuse for her being with her mother was that they were unable to get her to rest elsewhere. The little girl skinned freely and made a good recovery; the mother and infant did well; not a single occurrence took place to mar their convalescence. Subsequent to the mother coming downstairs, a second child took the disease and recovered. At no time were antiseptic or precautionary measures of any kind used.

I am, Sir, yours faithfully,

JOSEPH W. HILLES, L.R.C.P. & S.E.D.

Gargrave, Yorks, Sept. 4th, 1882.

**St. George's.**—Mr. Timothy Holmes, F.R.C.S., is surgeon-in-chief to the Metropolitan Police. Application should be made to him for the local appointment.

**W. E. B.**—Weiss and Co., 62, Strand.

**F.R.S.**—Fraser Brothers, Commercial-road East, London.

### "VENESECTION: WHY IS IT SO RARELY PRACTISED?"

To the Editor of THE LANCET.

SIR,—In your issue of the 26th ult. Mr. Reynolds scarcely answers the question, but I will presume to try. Because the actual operation of opening a vein is never witnessed by the student. Few men now probably doubt its value any more than I who graduated eight years ago, and merely saw it described minutely by the class tutor. One does not like to bungle in so simple a matter, and as the friends of the patient might not like the novelty of the proposition, a man would naturally wish to feel that he could do it nicely. I never, knowingly, met anyone who cared to attempt it, and am constrained to admit my own stupid feeling about it, though I never let minor operations pass me.

I am, Sir, yours faithfully,

BOTHERED

Sept. 11th, 1882.

**Perplexed.**—The course of gestation, and eventually of parturition, will not necessarily be influenced by the injury to the head. The safest attitude is one of cautious expectancy.

**Prof. Maclean** is thanked.

**Enquirer.**—The report appeared in the *Surrey Advertiser*.

### "THE POSITIVE TREATMENT OF GONORRHOEA."

To the Editor of THE LANCET.

SIR,—In an article on the above subject in THE LANCET, Sept. 2nd, your correspondent, "M.R.C.S. Eng." omits to state the method of exhibiting the infusion of cubeb and iodide of potassium, &c., as to the quantity and time of administering each dose. In publishing so obviously valuable a prescription, I venture to state that "M.R.C.S. Eng." would benefit many of his brother practitioners by rectifying this omission.

I am, Sir, yours, &c.,

H. B.

Sept. 4th, 1882.

## "MORBUS CORDIS."

To the Editor of THE LANCET.

SIR,—Mr. H. M. Tuckwell will find the lines published at 377 in THE LANCET of August 26th in *Punch* (last volume of 1880), in one of the last numbers for November or first number of December for that year. I remember reading them in a *Punch* that arrived about Christmas of that year at a station in India I was then living at. The "lines" were accompanied with an illustration in which a gentleman patient was sitting in an arm-chair in a dressing-gown spouting the verses, with his hand tightly grasping the region of the heart when his lady doctor came to see him with her phials of drugs. On his countenance was also depicted a very earnest, supplicating expression. I am afraid his patient, the ship's engineer, if he means to appropriate them to his own genius, is guilty of plagiarism (unless he contributed them to *Punch*). I have no volumes of *Punch* by me, but the verses, if not word for word, must be very nearly what appeared in that journal about the time I have specified.

I am, Sir, yours, &c.,  
Leeds, Sept. 4th, 1882.

E. HOPKINS, Surg.-Major.

To the Editor of THE LANCET.

SIR,—A friend, who has read the lines on the "lady doctor," in last week's number of your journal, calls my attention to the fact that they have already appeared in *Punch*. It seems, therefore, that they must be taken rather as an instance of good memory than of original power of composition in right-sided hemiplegia.

I am, Sir, your obedient servant,  
Oxford, Sept. 5th, 1882. H. M. TUCKWELL.

Australian (Liverpool).—E. L. Crowther, M.D. Aberd., L.R.C.P. Ed., referred to in THE LANCET of the 2nd inst. as having been re-elected Member of Parliament at Hobart, Tasmania, is also a M.R.C.S. Eng., and is a son of another member of the Legislature—viz., Mr. Wm. Lodwyk Crowther, F.R.C.S. Eng., to whom the Council of the Royal College of Surgeons presented the Honorary Gold Medal in 1869 for his many and valuable contributions to the Museum of the College. Of the six recipients of this medal since 1800, only two remain—viz., the octogenarian, George Bennett, M.D., F.R.C.S., and Dr. Crowther.

N. A. P.—The fee should be equally divided.

Mr. Kenneth W. Millican (Kineton).—The manuscript has been received.

## "DISINFECTING DUSTBINS."

To the Editor of THE LANCET.

SIR,—I have read the article in your journal published on Sept. 2nd, page 363, on the above subject. I would most respectfully call your notice to the enclosed circular. It was from the constant complaints of nuisances arising from the non-emptying of dustbins that led to the manufacture of the "Combination Dustbin and Sifter." By its use all the troubles mentioned in your article are done away with. It is made entirely of galvanised iron, so that fires caused by hot cinders (a frequent occurrence) is impossible. It is intended to be wheeled off the premises every day to the dustman's cart and there emptied of its contents, which is a great saving of labour to the dustman and of litter caused by his repeated journeys with his basket. I may mention that eight of these machines are now in use in Greenwich Workhouse, and, with two on order, there will shortly be ten; and I am quite sure that Mr. Kelly, the master, will be pleased to show them to anyone in operation. The stationary dustbins on this establishment have been entirely dispensed with.

I am, Sir, your obedient servant,  
London, Sept. 6th, 1882. THOS. P. COOK.

\*. From the diagrams in the circular, the "Combination" Cinder-bin and Sifter appear to answer the purpose intended.—ED. L.

Mr. C. A. Jones, L.R.C.P.—Our correspondent will get all information he desires on application to Mr. H. S. Carpenter, 130, Stockwell-road, S.W.

E. Tery (Liverpool).—The London University.

## DRINKING WATER—PURE OR IMPURE?

To the Editor of THE LANCET.

SIR,—In the *Daily Telegraph* of Friday last I read the following under the head of "Bangor":—

"With respect to the water, which has been so strongly condemned by the district officer of health as being impregnated with fever germs, a report was read from Dr. Muter, South London Laboratory, who at the request of the board had analysed six samples of the water taken at points where the fever was most virulent. All these, with one exception, were of good quality and drinkable."

In a large establishment I know well, typhoid has been prevalent for a long time, and the water has been analysed by two eminent men, one of whom said the water was pure, the other condemning it in toto. Now, I would ask, if these things be so, how are we to determine accurately whether or no our water is pure? Are we not drifting into greater difficulties and troubles on these matters when we find eminent analysts totally differ than when we knew less, and probably took as much or more care, but in a less scientific manner.

I am, Sir, your obedient servant,  
Sept. 11th, 1882. AQUA.

## MILK ANALYSIS.

THE magistrates of Great Yarmouth had recently before them a milkman who had refused to sell milk to an officer of the local sanitary authority for the purpose of analysis. The case having been proved, and the defendant having been convicted for selling adulterated milk last year, he was fined 40s. and costs.

O. (St. Bartholomew's).—No introductory has been delivered at this hospital for some years past, instead of which the "old students" annual dinner" will take place, by permission of the governors, in the Great Hall of the hospital, on the evening of Monday, Oct. 2nd, when Dr. R. Martin will occupy the chair, to which several visitors have been invited.

Mr. Chalmers (Liverpool).—The chief medical officer to the General Post Office is Dr. Waller Lewis; Mr. G. Carrick Steet, F.R.C.S., is the second.

L.R.C.P. (Edinburgh).—The late Mr. Liston died before his turn came to be elected President of the College.

THE letters of Dr. Henry Walker and Mr. E. D. Tomlinson arrived too late for insertion.

L. S. D.—Yes. Our correspondent has the right to give a certificate.

Mr. Edward Ward.—The blocks should be sent with the reports.

Dr. Haughton's letter shall receive attention.

## "AN EXTRAORDINARY CASE OF EARLY PUBERTY IN A BOY."

To the Editor of THE LANCET.

SIR,—It has occurred to me that the extraordinary child, described by Mr. T. Woods in THE LANCET of Sept. 2nd, might have expressed himself at birth somewhat in the following style.—I am, Sir, yours, &c.,  
Sept. 6th, 1882. TOPSY-TURVY.

Doctor, I this world have entered  
At the wrong end of my life;  
All my thoughts on crime are centred,  
And my tongue's with curses rife.

Doctor, can your deed be pardoned?  
Could you ever have done worse?  
Here you've brought me—old and hardened,—  
I've assassinated nurse!

Doctor, as the years roll over,  
I can only younger get;  
Dotard, warrior, and lover,  
Each in turn I must be yet.

Crutch and toothpick left, the dandy  
Unto marbles must descend;  
And at sixty, sugar-candy,  
Measles, pap, and milk will blend.

Till a bearded baby ending  
After threescore years and ten,  
Folks will bless me, o'er me bending,  
For I shall be guileless then!

John Jackson.—The prizes are confined to members of the College, who alone can compete for them. Write to the secretary.

Oculus should consult the article in the new number of the Royal London Ophthalmic Hospital Reports, just published.

Inquirer.—Next week.

Query.—Yes; legally bound to give a certificate without charge.

OUR correspondent from Stockport has omitted to enclose his address.

## "OUGHT DISEASED MEAT TO BE USED AS HUMAN FOOD?"

To the Editor of THE LANCET.

SIR,—In reply to your correspondent on the above subject, I venture to say there can hardly be two opinions as to whether he was justified in condemning the meat under the circumstances described. A strong point in favour of the cow being diseased was the fact of slaughtering so soon after parturition. The prosecution, in cross-examination, might have elicited a reason for this, and should also have objected to the admission of the medical evidence for the defence, the witness never having seen it, and therefore unable to judge. It would have been interesting to know the condition of the calf—whether still-born, ill-nourished, or the like. It is always advisable to examine as much as possible both the flesh, including fat, and the offal, since, as in the last case occurring in my district, the "most marketable" pieces are retained for sale, while the rest are thrown along with the offal or buried in the manure heap, the offal most frequently affording the best evidence of disease. It has been my practice to advise the local authority to procure the additional opinion and evidence of some duly qualified veterinary surgeon, which materially aids the "case for the prosecution." Wilson's Handbook of Hygiene (sixth edition) contains some useful information on this subject. May not the result in this instance be looked upon as a "miscarriage of justice?"

I am, Sir, yours respectfully,  
Sept. 6th, 1882. NATHAN HANNAH.

## Lectures ON THE

# MECHANISM OF RESPIRATION IN PHYSIOLOGICAL & PATHOLOGICAL CONDITIONS.

*Delivered before the Faculty of Physicians and Surgeons of Glasgow.*

By D. O. McVAIL, M.B.,

FELLOW OF THE FACULTY, AND LECTURER ON MEDICINE IN THE GLASGOW WESTERN MEDICAL SCHOOL.

## LECTURE I.—PART I.

MR. PRESIDENT AND GENTLEMEN,—In the year 1816—the year after Waterloo—a circumstance occurred in Paris that in its results has been of greater and more enduring importance to mankind than any or all of the turbulent events which that city had witnessed in the preceding forty years. That circumstance was the appointment of Laennec to be physician to the Necker Hospital. He was then in his thirty-seventh year. He had undergone a training in professional subjects, and in the physical sciences collateral thereto, of a kind that in his new position enabled him to observe and to reason on the phenomena of disease which then came under his notice with a comprehensiveness and exactitude that have never been surpassed in the long history of medicine. In the first two years of his hospital work he made that marvellous application of mediate auscultation as interpretive of pulmonary conditions that still fills the mind of every reader with amazement. The breath-sounds of health and disease revealed to him by his newly-invented cylinder or stethoscope he explained and classified so truthfully, and in language so simple and accurate laid his work before the profession, that it at once almost became common property, and physicians everywhere have listened and spoken of pulmonary sounds just as Laennec did, hearing what he taught them to hear, and talking and writing of their cases in the terms that he first employed. So completely have his views been established, and so universally in the profession have they been received, that at the present day the hospital physician and general practitioner with almost equal facility and exactitude ascertain whatever of functional or structural change can be deduced from the respiratory sounds. But during all those years, while the *acoustics of respiration* have led the physician, by formerly untrodden ways, to new regions of knowledge, even more and more sharpening the accuracy with which he can observe and practically deal with many of the pathological changes that occur in the minute recesses of the pulmonary structure—in all those eventful sixty years how small has been the aid afforded to clinical work by the mechanics of respiration. And this extraordinary discrepancy is all the more wonderful that for years past so many of the physiological mechanisms have been subjected to most searching investigation by methods and appliances as rigorously exact as have been used in any department of scientific inquiry. The rate at which the blood travels in the arteries, the speed of the pulse-wave, the rapidity with which a stimulus is carried along a nerve-fibre, have all been determined with very great accuracy. The weights respectively that press on the aortic and pulmonary valves, the number of impulses that in a second flow from the nerve-centres to a muscle that is in action, the minute fraction of time that is required for the molecular changes in the cells of nerve-centres concerned in reflex acts,—all these we can express in exact arithmetical terms. But I need not in this hall adduce instances of physiological triumphs in the investigation of the living mechanical processes, as we have a most perfect recollection of the brilliant description and demonstration of these given us by Dr. McKendrick in the first course of Faculty lectures. And many of these discoveries are now of more than mere speculative scientific interest, having already been waited for by the physiologist's laboratory to the wards of the physician, and taken permanently on the yoke of practical service in the healing art.

Very wonderful, then, it must appear that in the clinical  
No. 3082.

work of the most highly cultured and most advanced physicians in this country at the present day scarce more aid is received from respiratory mechanics than was the case thirty or even forty years ago. But this department of inquiry has by no means been entirely overlooked. At various times, by different forms of stethometers, the breath movements have been measured, and lengthy tables of such measurements in health and disease have been with great patience and care constructed. And of late years instruments for recording by the graphic method in various ways these movements have been called in aid, and many interesting observations have been made. One of the very earliest of these I had the pleasure of exhibiting, at a conversazione of the Faculty in 1868, and I then did not doubt that from its use important practical results would speedily come. But ere long I saw that before the graphic method could become of any great practical value to the physician, in so far as respiration is concerned, a prolonged and patient inquiry must first be made into many of the fundamental phenomena of the mechanism of breathing. In this field I have worked, as opportunity has offered and the exigencies of other duties have permitted, and in these lectures I shall have the privilege of bringing under your notice whatever of serviceable result I have obtained, or suppose I have obtained.

The Calendar of the University of Glasgow informs us that the present professor of chemistry is the ninth teacher who has there lectured on that branch of the medical curriculum. His seventh predecessor was Dr. Joseph Black, the discoverer of latent heat, whose portrait adorns the hall in which we are now assembled. But although Dr. Black owes his popular fame to that celebrated discovery, he made another contribution to science that concerns us much more nearly. He, in the year 1755, isolated and experimented on carbonic acid. He did not call it by that name, but spoke of it as "fixed air," from the circumstance that it could be absorbed and retained or "fixed" by quick lime and other bodies. Necessarily he was altogether ignorant of its chemical constitution, for the discovery of oxygen by Priestley was then nineteen years away in the future. Yet does his work form an epoch in the history of science, for he showed this gas to be different entirely from common air, that it might be united with certain bodies greatly altering their qualities, and set free from them again by appropriate means; and among other facts regarding this gas first disclosed by him were these, that it is expired from the lungs of animals, and that in the lungs common air is partly converted into fixed air. He thus prepared the way for the final exposition of the chemical composition of this gas by Lavoisier, and the further brilliant demonstration by that great philosopher of the essential chemical change that occurs in respiration.

Prior, then, to the time when, by the genius of Black, a glimmer of true light was thrown on the chemistry of respiration, what could have been the views entertained with regard to the mechanism of breathing? At that time, the middle of last century, although microscopic anatomy could scarcely be said to have any existence, macroscopic anatomy was not so very much in arrear of what it is at the present day. That generation, and their predecessors, for nearly four hundred years had been enthusiastic dissectors of the human body, and in 1727 there was sufficient anatomical and physiological material to enable Hamberger to lay a sure foundation of respiratory mechanics in the celebrated essay which in that year he published. But to understand clearly the work done by him and since his time, it is necessary to glance briefly at the labours of the greater of his predecessors, and the investigations that up to his day had been made.

In those first writings in medicine—the works of Hippocrates—we find but a passing allusion to the respiratory mechanism, where he speaks in his book on the "Articulations" of the "cavities which inspire and expire the breath." A century later an attempt at a scientific theory of respiration was made by Aristotle, who taught that in the heart heat was constantly being produced, and as heat causes whatever it acts on to expand, the heat of the heart made the lungs that surround so much of its surface to expand to a very notable degree, so much so as to push outwards the thoracic walls, and so he said inspiration was effected; but the lungs being expanded cold air from without entered them, reducing the temperature, and so causing the lungs again to contract, and thus the return movement of expiration came about.

The views that Aristotle expressed on this and other biological subjects led, in that brilliant period of intellectual

activity, to considerable attention being devoted to human and comparative anatomy; and soon after his time Erasistratus discovered the connexion of the trachea with the lungs, and its use in the conveyance of air into them; and Herophilus discovered the pulmonary artery and the pulmonary vein, and their connexions with the heart and lungs, calling the pulmonary artery of modern anatomy the "arterial vein," and the pulmonary vein the "venous artery." Pondering over these new anatomical revelations, Erasistratus propounded a most ingenious theory of breathing. Still assuming, with Aristotle, that the lungs were caused to expand by heat generated in the heart, he said the air entered by the trachea into the lungs, and then found its way along the ramification of the air-passages to their ultimate terminal twigs, from which it passed into the minute terminal branches of the pulmonary vein—"venous artery," as he termed it—and thus was conveyed to the left side of the heart, to be by it sent into its own system of vessels, the arteries or air-ducts, to feed the textures of the body with vital spirits, which vital spirits in the tissues, meeting with the blood brought by the veins concocted with the blood, and by due concoction gave rise to bile, black bile, phlegm, and all other necessary animal products.

This theory of respiration was universally received for five hundred years, until exploded by Galen, for the anatomists during that long period made no special investigation of this department of the science. Marinus dissected in Rome in the century before Christ, Aretæus a hundred years after Marinus, and Rufus of Ephesus again after Aretæus; but there is no record of their having done anything to elucidate further the phenomena of respiration, although undoubtedly demonstrations made by Marinus regarding the structure and functions of certain of the glands throw very valuable side-light on the subject. But in the second Christian century was born Galen. He made himself master of all that had been done in science prior to his time, and by dissection, experiment, and observation he added so much thereto that his position in medicine was, in the estimation of men for hundreds of years, scarcely second even to that of Hippocrates himself. In his writings for the first time we are taught that the increase and diminution of the thoracic cavity in respiration, are owing to movements of the thoracic walls due to muscular action, and not to expansion of the lung by heat, as was fancied by Aristotle. This correction by Galen was an enormous step in advance, and thenceforward nothing more is heard of the older view of the Greek philosophers. By Galen also for the first time were described the intercostal muscles in their two layers. To the external set he attributed an expiratory function, and to the internal an inspiratory function—a view of the matter that remained undisputed for fourteen hundred years, until in the sixteenth century it was modified, as we shall presently see, by Vesalius.

In the theory of respiration given to us by Erasistratus the arteries are described as carrying air only. Galen now showed that the arteries contained blood, were filled with blood. He seems to have believed that the arterial and venous systems equally received vital aerial spirits at the lungs—the one by the venous artery, the other by the arterial vein; and he supposed further that the arteries contained a purer blood than the veins, this purer blood being for the supply of the more important parts, such as the brain; and he also taught that the arterial and venous bloods were confined for the most part to their respective systems of vessels, but that a communication or mingling of them to a limited extent took place through the muscular septum of the heart; and his imagination was strong enough to show him pores in the cardiac septum through which the blood passed from the one side to the other; and this power of imagination became hereditary, for all the anatomists who succeeded him saw these pores for fourteen hundred years, until Vesalius showed that such did not exist. In spite of errors that at the time in which he lived were inevitable, his labours form an epoch in the history of medicine; in anatomy and physiology, especially, the advances made by him were great, and doubtless he expected that those coming after him would rapidly improve on what he had done. But the spirit of scientific research became for the time extinct with Galen, and for nearly a thousand years no one made any additions to our knowledge of anatomy or physiology, whether human or comparative. During this dark period the Arabians alone retained some slight relish for scientific subjects. They preserved, and in their own way revered, the writings of Galen and Hippocrates; but their minds were chiefly given

to the study of astrology and alchemy, and endeavours to find the philosopher's stone and the elixir of life. These matters were what chiefly engrossed the attention of the scientists of Bagdad. But in the eleventh century there came to Bagdad a stranger from Carthage, in Africa, who, in the Arabic metropolis, for thirty years studied diligently all that was known of the sciences in general, and medicine in particular. This student, Constantine, subsequently found his way to Sicily; carrying back with him to the west the learning which the Arabians had originally obtained from it, and in the medical school of Salerno, that had been founded in the seventh century by Benedictine monks, he became a diligent teacher of medicine. He was the author of two medical works that were printed five hundred years afterwards, and of which the Faculty library possesses copies in excellent preservation. The seed of knowledge he sowed in Sicily did not immediately bear fruit, but it did not die, for after a germination period of fully three hundred years it resulted in the revival of anatomy in Europe by Mundinus, who was professor in Bologna in 1316, who made dissections of the human body, and who began those demonstrations to students in practical anatomy that have been continued down to the present day. He wrote a book on the subject that afterwards, in 1478, was printed in Pavia, and which, so far as I can make out, was the second medical work ever printed, and of which I am sorry to say our own library has not a copy. The University of Glasgow possesses a copy of the first and of several succeeding editions. This book, in transcriptions at first, and subsequently in print, became the general text-book of anatomy, and from his time onwards in most universities in every session dissections were made and the parts demonstrated according to Mundinus. This author did nothing for the anatomy or physiology of respiration, and seems to have attached but little importance to the investigations of Galen regarding the intercostal muscles. For about a hundred years anatomy remained as Mundinus left it, until towards the end of the fifteenth and the beginning of the sixteenth centuries important contributions were made to it by De Zerbi, De Carpi, Achillinus, and Montagnana. As directly bearing on respiration, the labours of these men amounted to little, except in the case of De Carpi, who in 1518 discovered the tricuspid valves and the semilunar valves at the origin of the pulmonary artery. In 1536 Charles Etienne discovered the valves of the veins.

In the year in which the work of Mundinus was first printed (1478) was born one of the most celebrated of the anatomists of the period of which I am now speaking—James Du Bois Sylvius, who became professor in the College of Tricquet, founded in Paris by Francis I., and in it taught anatomy with an enthusiasm and success far beyond that of any of his predecessors. He published two works that in their day attracted much attention, and he also took part in a disputation with his greatly celebrated pupil Vesalius. The Faculty possesses his publications in the form of a quarto volume, published at Geneva in 1630.

Contemporary in anatomical work with Sylvius, although in age twenty-six years his senior, was a man who in another walk of life attained to the foremost rank of fame—Leonardo da Vinci. He made many dissections, and of these he made drawings to illustrate demonstrations on anatomy by Marco Antonio della Torre, who was professor at Pavia. These drawings, which are in red chalk and touched up by a pen, were in the time of Pilkington in the possession of George the Third; and in 1790 some of them were engraved and published in London by Joseph Chamberlain. Our library has no copy of this.

In 1514, at Brussels, was born the greatest of all the anatomists of this period—Vesalius. He studied anatomy in Paris under James Sylvius. He possessed great mental originality and daring, and was the first who had the courage to differ in some important matters from the teaching of Galen, whose word on all points on which he had spoken until then was regarded as infallible. So able were the observations made by Vesalius, and so famous did he become, that he excited the jealousy and animosity of his master, Sylvius, who controverted the new views, arguing that all was true that Galen had taught. This celebrated discussion had reference chiefly to the structure of the sternum, the bones of the arm, the presence or absence of pores in the cardiac septum, and the action of the intercostal muscles. He was a most accurate dissector, and especially did he give great attention to the muscular system. In 1535, and again in

1543, he published a series of anatomical plates, that were drawn for him by no less a personage than Titian, who, like Da Vinci, was an accomplished anatomist. Our Faculty library has no copy of these early editions, but has one edited by Boerhaave and Albinus, and printed in 1725.

In these writings, after a lapse of fourteen centuries, the views of Galen regarding the actions of the intercostal muscles were called in question. Galen taught that the external layer was expiratory, and the internal layer inspiratory. Vesalius objects to this, and says both are inspiratory, and act simultaneously. But his idea of their action is certainly far from clear, for he says they act by drawing the contiguous ribs towards one another, the external layer drawing the lower of two ribs towards the one above it, and the internal layer drawing the upper towards the lower. Between the costal cartilages he also supposed there were two layers of muscular fibres decussating with one another, and of these he says the external layer draws the higher cartilage to the lower, and the internal the lower to the higher.

Following Vesalius came his pupil Fallopius, who in Pisa was professor of anatomy for many years. His observations were extremely accurate, and he corrected many of the errors of his predecessors. Among others, he first showed that between the costal cartilages there is but one layer of muscular fibres, and not two, as until then had been supposed. He published two important anatomical works in 1561 and 1571, and of these the Faculty has a reprint dated 1600.

In the time of Fallopius there lived a man who in an erratic way gave considerable attention both to theology and medicine—Michael Servetus, a native of Aragon, born in 1509. In a very extraordinary book, entitled "*Christianismi Restitutio*," that he published in 1553, he for the first time gave a true account of the circulation of the blood through the lungs, asserting that all the blood passed from the right to the left side of the heart by a long and marvellous course through the lungs. This great discovery, however, received then but little attention, and as he had given utterance to some religious opinions that Protestants then deemed heterodox, Calvin burned both him and his book at Geneva, where he had incautiously come, although previously warned to keep as far from the clutches of that religious reformer as he possibly could.

Contemporaneous also with Fallopius, who taught at Pisa, was the great Eustachius, who was professor at Rome. Most comprehensive and precise were his dissections, and his descriptions of them. In 1563 he published his "*Opuscula Anatomica*." In this work, that was held in great esteem, he speaks of a large series of drawings he had made, and was engaged in engraving with his own hand on copper. At his death, to the great regret of all, these could not be found, and they remained lost for 150 years, when they were discovered, and under the editorship of Luncini, physician to Pope Clement XI., were for the first time published in 1714. Of this celebrated first edition the Faculty library has a copy in splendid preservation. An examination of these plates shows that, with the exception of the lymphatic system, Eustachius was, in the middle of the sixteenth century, almost as well acquainted with the leading points of the ordinary anatomy of the body as we are at the present day, and more especially was his knowledge of the muscles, and many of their actions, wonderfully accurate; the intercostal muscles he represents most truthfully. It was not, however, until 1597 that the muscles generally received from Gaspard Bauhin the names by which they are known to us. Until then they were chiefly spoken of as in layers and pairs, each of these layers and pairs having a special number.

So thoroughly had Eustachius and his contemporaries of the sixteenth century and their predecessors investigated and described human microscopic structure, that in the following hundred years almost the only additions made to anatomy were the discovery in 1621 of the lacteal vessels by Asselli, and the thoracic duct and general lymphatic system by Picquet in 1654. So very complete, indeed, had this science become, that the "*Institutes of Anatomy*" by Caspar Bartholinus, published in 1611, continued to be the general text-book of the subject until 1693, when it was pushed out of the field by a new work by Philip Verheyen.

By the labours, then, of the distinguished men of whom I have spoken, continued during hundreds of years, the science of anatomy by the beginning of the seventeenth century was so advanced as to afford materials for the foundation of a

rational and exact system of physiology; and soon by a master hand was laid the cornerstone, for in 1619 Harvey announced his discovery of the circulation of the blood.

From this time the various physiological actions received very special consideration, and the mechanism of respiration soon engaged the attention of three of the most eminent members of the profession in the century of Harvey—namely, Thomas Willis, John Alphonso Borelli, and John Mayow. Thomas Willis was a native of Great Bedwin in Wiltshire. He studied medicine in Oxford and practised his profession in that city, and subsequently was appointed Sedleian professor of natural philosophy in the university. His medical writings are numerous and important; more especially is he

FIG. 1.

remembered for his great work on the nervous system. But he also made a most important contribution to respiratory mechanics, for in his *Pharmaceutice Rationalis*, printed in 1673, he, for the first time, advocated the view that the external intercostal muscles are inspiratory, and the internal expiratory, which led in the following century to the famous discussion between Hamberger and Haller.

At Castlenuovo, in Naples, was born, in 1608, Borelli, who became an accomplished mathematician and physiologist, and employed mathematical principles and reasoning in explaining the functions of the animal body. In 1656 he became professor at Pisa. He published many works, the most celebrated, "*De Motu Animalium*,"

FIG. 2.

being printed in 1680, the year after his death, at the expense of Queen Christina. In this treatise for the first time is explained, with anything of scientific exactitude, the manner in which by elevation of the thoracic walls the internal capacity is increased. Here I reproduce a drawing that he gives in explanation of this. (Fig. 1). He represents the costal arch as articulating with the spine, the upper angle of articulation, A, being more, and the inferior angle, B, less than a right angle; and he argues that necessarily on the arch, A, B, C, being elevated towards a right angle, the antero-posterior diameter is increased. He enunciated this pretty much in the following manner:—1st. If in two extremities, A and C, the

semi-elliptical arc, A, B, C were fixed to the wall F H; if the arc were drawn upwards to the perpendicular, from B to E, then E has more receded from the wall than B. 2nd. If (Fig. 2) of several semi-elliptical arcs the extremities A, D, H are fixed to the firm column P S, and the extremities C, E, I to the immovable wood, Q R, and the planes of the equidistant arches form acute angles with the plane P R; if the apices of the arches, B O M, are drawn in the direction M B, so that the acute angles become more obtuse, the semi-cylindrical cavity, A, B, C, I, M, H, is made greater. That anatomists until his time had most obscure views of this matter is beyond doubt, for in the general textbook of anatomy then in use, that by Caspar Bartholinus, published in 1611, and in which the author evidently supposes (although erroneously) that he gives the views of Vesalius, he says of the external intercostals that by elevating the thoracic walls they constrict the chest, producing expiration, and the internal intercostals widen the intercostal spaces, and produce inspiration. Borelli certainly, for the first time, gives a rational explanation of the effects of elevating and depressing the chest walls. As regards the intercostal muscles themselves, he supposed both layers to be inspiratory, and never expiratory.

### ON THE INVISIBLE CORPUSCLES OF MAMMALIAN AND OVIPAROUS BLOOD, AND THEIR RELATION TO FIBRIN FORMATION AND COAGULATION.

BY RICHARD NORRIS, M.D., F.R.S.E.,  
PROFESSOR OF PHYSIOLOGY, QUEEN'S COLLEGE, BIRMINGHAM.

(Concluded from page 431.)

THE question as to whether the blood of the ovipara possesses a corpuscle which is the analogue and equivalent of the invisible disc of the mammal blood has received at my hands a great amount of attention. I have examined the point not only in the blood of batrachians, but in that of fishes and birds, and I have arrived at the conclusion that in all ovipara a corpuscle exists which corresponds precisely, in its anatomical characteristics, in its developmental position, and in its disintegrative modifications, with the invisible disc of the mammal blood. Such bodies will be found to be treated of in my work on the "Physiology and Pathology of the Blood," sections xi. and xii., p. 184, under the head of Colourless Nucleated Ellipsoids, and it is there explained that these are the analogue of the advanced lymph, splenic, and bone-marrow corpuscles, and therefore of the invisible colourless discs, of the mammal. I have also pointed out that these bodies may be seen developing in the spleen and bone-marrow of the ovipara as their obvious products.

At the time Professor Legge wrote his memoir I do not think he could have read my second letter in THE LANCET in reply to Professor Bizzozero, and certainly he could not have seen my book, in which I have shown that all the conditions of error to which he refers have been avoided. It is unnecessary to follow this author into the question of the effects of water or water-vapour upon the blood-corpuscles; they are well known, and have been fully treated of in my work, and their influence has been absolutely excluded from all my experiments. I should never have dreamed of using to dilute blood in which I desired to make a demonstration any artificial solution whatever, not even the so-called physiological solution used by Professor Legge, which I presume to be a three-quarter per cent. solution of sodium chloride, a solution which I have found to be very active in decolourising mammal discs. Every physiologist knows that the serum of one blood will dissolve the corpuscles of another, and surely with such a fact before us we should refrain from adding any foreign solutions to the blood. The bodies which Professor Legge has seen in the oviparous blood, which he has taken from the moist skin of the animal, or after the addition of water or of his physiological solution, are, as he truly states, nothing more than decolourised red corpuscles; but they have nothing in common nor anything to do with the invisible oviparous corpuscles (the existence of which in

oviparous as in mammal blood I am the first to make known).<sup>1</sup> In order to demonstrate the existence of the invisible corpuscle of the mammal or of the ovipara, the blood should be examined immediately after it is shed, and without the addition of any foreign liquid whatever to it, and as an additional security it should be taken, not from the moist skin, but from the left ventricle of the heart. If under these conditions persons fail to find these bodies, it will be because they have not acquired the necessary technical skill which springs from prolonged study of a subject, and which experiment and trial can alone furnish them with.

The elements which Professor Legge has seen in oviparous blood, and which he believes to be analogous to my invisible discs in mammal blood, are, as I have before stated, corpuscles which he has decolourised by his inadmissible methods of investigation. The real invisible corpuscle is, of course, neither to be seen either in the circulating blood or when that blood is shed, but is capable of being rendered obvious by various indirect methods, which do not and cannot involve decolourisation of red corpuscles; and, further, red discs or oviparous corpuscles, which have been purposely deprived of their hæmoglobin, can readily be distinguished by certain definite characteristics which they possess from the true invisible disc or corpuscle. To the statement of Professor Legge, that the invisible corpuscle cannot escape observation in the circulating blood on account of its excessive delicacy, "because when we are forewarned it is possible to observe a detail, however delicate," I entirely demur. This might be true of a body or of details which could barely be seen, or be seen only with great difficulty, but it is absolutely inaccurate in the case of elements or substances, which have precisely the same colour and refractive index as each other. The material which forms the invisible mammal disc and the invisible cell body of the oviparian corpuscles cannot be seen by the most careful management of lenses and illumination, neither can it be photographed<sup>2</sup> either in the circulating blood or when this has been shed, and yet, being substantive, can be rendered obvious by packing other highly plastic bodies, such as their fellow red corpuscles, around them; but, as I have elsewhere pointed out, this can only be done when they have effected adhesion to the slide, for under other circumstances their limpid, liquid, flowing character is so marked, and the shapes they take on so protean and multiform, that they cannot be detected from pure liquid matter. Under these circumstances other and unobjectionable methods are open to us, of which I will shortly speak. Because, therefore, we cannot see these corpuscles in the circulating blood of the mammal or ovipara, we are not justified in assuming their absence, for if they could be seen our position respecting their nature would be vitiated. We shall, in fact, never see them in the circulation, unless some staining agent can be found which, when introduced, affects them preferentially and leaves the red discs uninfluenced, or unless certain pathological changes of the blood reveal them by rendering them granular or altering the relative refractive indices of the corpuscles and liquor sanguinis, or unless some exceedingly fine deposit can be introduced into the blood which will adhere to them; or it may be that they may ultimately be observed inside the vessels, by bringing about packing in small capillaries, but this is scarcely likely, for unless, as I have previously pointed out, they adhered to the walls of the vessels, their circular shape would not be retained. What can, however, be observed in the circulating blood, both of the mammal and of the ovipara, is that the red discs are not all of one standard degree of colour, and that some are so pale as scarcely to be visible. Such pale corpuscles of course cannot be said under these conditions to have lost their hæmoglobin by manipulation or moisture, and the inference is warranted that such corpuscles are either gradually losing or attaining colour in the circulation, and, in either case, such a state of things would lead to the assumption that there were corpuscles in the blood too pale to be seen. Of course, it may be argued that the corpuscles do not necessarily attain to a given standard of colour; but it must be admitted that this is most likely to be the case, and if the corpuscles do acquire colour gradually in the blood, the whole case is made out; for as some are scarcely visible, there must then be also a colourless and invisible stage. We see therefore how illogical is the assumption that because these bodies cannot be seen in the circulation they are therefore absent. If

<sup>1</sup> Physiology and Pathology of the Blood, p. 184. (Smith, Elder, & Co.)

<sup>2</sup> Bodies which cannot be seen may, notwithstanding, frequently be revealed by photography.

conditions could be obtained in the circulation similar to those which can be obtained externally, they would be equally obvious.

It is, of course, most desirable to possess absolute proof of the existence of these bodies in the circulating blood, because the question of the normal existence of the invisible corpuscle would then be completely set at rest, and the various theories as to loss of hæmoglobin by visible corpuscles for ever disposed of. Fortunately, although this cannot be had at present with the invisible disc of the mammal, it can be obtained in the case of its analogue and equivalent, the invisible corpuscle of the ovipara; for while the cell-body of this corpuscle is absolutely invisible both in the circulation and outside the vessels, its nucleus can be far more easily seen than that of its fellow, the red corpuscle, under either of these circumstances; and therefore all we have to do is to identify this nucleus in the circulation, which here appears to be altogether free, and having ascertained that by no means at our command can we detect the slightest indication of a cell-body in connexion with it, we can again examine the same blood when shed, re-identify the nucleus, and again assure ourselves that we are unable to see the cell-body, although around some nuclei of a precisely similar appearance we can recognise a barely visible cell-body, and around similar nuclei other more strongly-tinted cell-bodies, which form the link between these and the ordinary full red corpuscles. Now, observe, we have here exactly the converse of a case of decolourisation. In the circulation and outside it we have certain oval or elliptical nuclei, which are granulated and highly refractive, and which we have not the least difficulty in identifying, either within the vessels or outside them, and the cell-body of which is absolutely invisible under both conditions, and so limpid and liquid-like that it offers no obstacle whatever to the pressure exerted by any other corpuscles allowing such to come into contact with its nucleus; in fact, behaves to all appearance like a free element, for which indeed it has always been taken. Now we will render this cell-body and the fibrin which it gives rise to (for it is the true fibrin factor of oviparous blood) obvious by a simple experiment, in which no pressure, no manipulation, no violence, no moisture, or solution of any kind is involved. Place upon a slide a drop of alcoholic solution of magenta, spread it with a glass rod, and allow it to dry thoroughly; you have now a delicate layer of magenta pigment. Place a drop of the blood intended for examination upon the cover-glass, and lower it very gently upon the slide; if this is not done gently, all your delicate cell-bodies will be converted by the motion into fibrin. In a little while the blood liquid will dissolve some of the magenta; the delicate cell bodies around the nuclei remain unstained, but the stained liquid around them and in contact with the slide differentiates them by contrast: the nuclei themselves become stained; the red corpuscles and their nuclei, even the palest visible kind, remain unaffected, or if affected at all the nuclei of the very palest become stained to a slight degree, thus affiliating themselves to those of the invisible ones. Nothing has been added to the blood calculated in any way to alter the red corpuscles; nor are they altered, not even stained by the magenta, for the amount of magenta dissolved by the blood liquid is either too inconsiderable to colour the red corpuscles, or is absorbed as rapidly as it is dissolved into the serum by the nuclei of the invisible corpuscles. In the ovipara, therefore, all the bodies which can be seen in the circulation can also be seen externally to it; but one of these can be shown to possess a cell-body, which is neither visible before or after the blood is shed, till brought into view by appropriate means. The blood of the triton and salamander, in fact of the ovipara generally, contains in the shape of morphological elements—1. Red nucleated corpuscles, which exist in various grades of colour, from very pale scarcely visible ones to full red. 2. Ordinary white corpuscles, which, being derived from the primary lymph, splenic, and bone-marrow corpuscles, contain one or several nuclei, and which correspond to the white corpuscles of the mammal. 3. Free shed nuclei of the above white corpuscles, which correspond to the shed nuclei of the white corpuscles of the mammal, which give rise to the invisible discs connected with its minor mode of development. These shed nuclei in the ovipara are nucleated, and develop into red corpuscles through the stage of Hayem's corpuscle (so-called oviparous hæmatoblasts). 4. Hayem's corpuscles (so-called oviparous hæmatoblasts), in their more developed state of visible oval nucleated corpuscles, free from

hæmoglobin. 5. Elliptical nuclei (apparently quite free), which belong to the invisible corpuscles of the ovipara, which correspond to the invisible corpuscles of the mammal, and, like them, are derived from the spleen, lymphatics, and bone-marrow. I have verified these results on the triton, fish, fowl, &c. The body which corresponds to the primary lymph disc of the mammal, and therefore to the blood-plates of Bizzozero, is a smaller nucleated body which comes over in small quantity into the blood from the lymphoid organs and develops in the blood, first into the uni-nuclear, and secondly into the multi-nuclear varieties of the white corpuscle. The greater number of these bodies yield by capsular disintegration free nucleated nuclei, which, growing in the lymphoid organs, pass into the blood as the fully-grown, colourless, nucleated ellipsoids.<sup>3</sup> This is what I have designated the major mode of development in oviparous blood, the minor mode being, in adult life, that described by Hayem and Pouchet. All this is made plain in Table I. and Plate 20 of my work.

There is a perfect analogy between the development of mammalian and oviparous blood—they both begin their career in a primary lymph corpuscle, the direct mode of development in which sets free a nucleus, which is simple in the mammal but nucleated in the ovipara. In the former, this nucleus passes into the blood, becomes its invisible disc, and ultimately gets colour, and shows itself as the pale red disc; in the latter case, the nucleated nucleus grows in the lymphoid organs, and having attained a certain size enters the blood, becomes invisible so far as its cell-body is concerned, while the nucleus remains visible; this body gradually attains colour, and presents itself as the palest order of oviparous corpuscles; this is the major mode of development. In addition to this, it happens that a few of the primary lymph corpuscles come over into the blood before they have undergone their usual development in the glands; these develop into white corpuscles, the nuclei of which are shed, and in their turn develop into red discs or oviparous red corpuscles, as the case may be. Hayem's hæmatoblast (so-called) is the intermediate stage of this process in the ovipara. The corpuscles of the ovipara, like those of the mammal, are divisible into a fugitive and permanent group, and the changes which occur in the fugitive group in this case also yield the fibrin and determine coagulation.

The identity of the corpuscles seen by Bizzozero and the invisible discs rests in the fact that they both represent stages in the development of one and the same body; they are identical in the same sense as the boy and the man, and in no other; that is to say, the primary lymph discs are developed into the invisible discs. Now that the existence of the invisible disc of the mammal has been verified by so many observers, its opponents are driven to take refuge in the facile hypothesis that it is a decolourised red disc, and they are content to make this assertion without noticing, much more disproving, the many facts which I have brought forward to show the contrary. At a very early period I proved that these corpuscles were the producers of fibrin, and a recent writer<sup>4</sup> has by the use of my methods verified this conclusion, at the same time adhering to the view that these corpuscles are decolourised discs. This paper has been reported upon and its conclusions endorsed by no less an authority than Professor Klein;<sup>5</sup> hence both writer and reporter are committed to the opinion that coagulation and fibrin formation are due to changes in decolourised red discs.

Few physiologists will be disposed to accept this view and its consequences. Again, on those who deny the existence of the invisible colourless discs of the mammal rests the responsibility of discovering the equivalent and analogue of the invisible corpuscle of the oviparous blood, the presence of which can be demonstrated in the circulation owing to the fact that it possesses a visible nucleus. The latter corpuscle is without doubt a true constituent of

<sup>3</sup> Although usage makes it convenient to speak of the oviparous corpuscle as a cell, and sanctions the phrases cell-body, nucleus, &c., it must never be forgotten that its mode of development shows it to be in reality a nucleated nucleus, which has been shed by a true cell. In both mammals and ovipara the hæmoglobin is associated with nuclear matter, and in both cases the same nuclear matter before it becomes converted into hæmoglobin is the source of true fibrin. All red blood corpuscles therefore are modified nuclei, which in the case of the mammal are simple, but in the ovipara nucleated; hence there is no break-down in the analogy as generally supposed.

<sup>4</sup> Note on the Formation of Fibrine, by Mrs. Ernest Hart. *Quarterly Journal of Microscopical Science*, July, 1882.

<sup>5</sup> *Medical Record*, July, 1882.

normal living blood, and its fibrin factor when shed; and the mammal blood ought to, and does, possess its counterpart, and if this is not the invisible mammal disc it still remains to be discovered. In his third special morphological element Professor Legge has confounded together several distinct bodies, and as a consequence he has noticed inexplicable variations; thus he can occasionally stain up a nucleus, but generally not. In the former case he is dealing with the so-called oviparous hæmatoblasts of Hayem, which may exist either in the circular or fusiform state, and in the other with the nucleus of the invisible corpuscle. There are, in fact, in oviparous blood, no less than four colourless elements instead of, as supposed by Professor Legge, two only: 1. The uni-nuclear and multi-nuclear white corpuscles. The former in its least developed state corresponds to the primary lymph disc of the mammal; the latter to its ordinary white corpuscle. 2. The liberated nucleolated nuclei of the white corpuscle. 3. The so-called oviparous hæmatoblasts of Hayem, which correspond to the invisible disc yielded by the white corpuscle of the mammal, which is body No. 2 in a more developed condition, often possessing considerable colour before it is much grown, or markedly ovoid in form. 4. The invisible nucleated ellipsoid furnished to the blood, in a perfect state as to size and form, by the lymphoid organs. This corresponds to the invisible disc yielded by the lymphoid organs of the mammal, and like it becomes gradually coloured in the blood. In addition to the elements above enumerated are the ordinary coloured elements of the blood, which present all gradations of tint. The morphological elements of oviparous blood may therefore be regarded as five in number. The special element of Professor Legge includes three bodies: 1. The earliest or uni-nuclear state of the white corpuscle. 2. The liberated nucleolated nuclei of the white corpuscle, and its more developed forms, the so-called hæmatoblasts of Hayem. 3. The nuclei of the invisible oviparous corpuscles. As Professor Legge does not mention the important researches of Hayem and Pouchet in connexion with these colourless elements, I presume he is unacquainted with them.

#### CONCLUSIONS.

I. The corpuscles recently observed in the circulating blood of the lower mammals by Professor Bizzozero, and called by him "blood-plates," are not newly discovered bodies, having been previously described by Professor Gulliver in 1846, and later in 1872 by Professor Hughes Bennett, and more fully by myself in 1878 under the designation of "lymph discs." I have also shown that this corpuscle possesses its fibrin-forming powers by virtue of being one of a series of corpuscles which I have distinguished under the title of the "fugitive group," some of which are visible and others invisible in the blood. Of this series of corpuscles it is the earliest, and the one which yields the smallest amount of true fibrin, contributing more to the substance of the clot by furnishing granules, which adhere to the true fibrin and assist mechanically in the production of fibres, than in any other way. The true fibrin is not deposited, as usually held, from the liquid of the blood, but is the viscous, slimy, glairy, transparent material furnished by the fusion and coalescence of the more developed corpuscles of the group—viz., by the invisible, colourless, and barely visible, slightly coloured discs, which after the blood is shed undergo conversion into the well-known fibrin forms.

II. The elliptical corpuscles of the ovipara, like the discs of the mammal, are divisible into a permanent and fugitive group. The latter includes those ellipsoidal corpuscles the nuclei of which alone can be seen, and the cell-bodies of which are invisible both while the blood is circulating and after it has been shed, and also a few of those corpuscles the outlines of which have become visible by the delicate tinting of their cell-bodies with hæmoglobin. It is the cell-bodies of these corpuscles which furnish the true fibrin—i.e., the material which gelatinises when the blood is shed. As in the case of the mammal blood, these corpuscles are the product of a gradual development of a colourless element which can be traced back as far as the spleen, lymphatics, and bone-marrow, and which is the true analogue of the primary lymph disc, from which all the morphological elements of mammal blood are directly or indirectly derived. This parent colourless element of oviparous blood, therefore, corresponds to the so-called blood-plates of Bizzozero.

III. In his recent investigation, Professor Legge, having overlooked the invisible cell-body of the transparent, colourless ellipsoid of the ovipara, has seen its nucleus both in the

circulating blood and in blood removed from the vessels, and has described it as an independent body and the analogue of the plates of Bizzozero, never dreaming (as well he might not, for no one unacquainted with the analogies of development in mammal blood would be led to look for it) that there existed around, and enclosing it, an unseen cell-body as large in most cases as that of the full-grown red corpuscle. No stronger proof could be afforded of the truth of my views than such an oversight, or of the incorrectness of Professor Legge's statements that no objection can be made to his conclusions "on the ground of excessive delicacy, because when we are forewarned it is possible to observe a detail, however delicate." Professor Legge has unwittingly demonstrated the truth of the position as to the absolute invisibility of these corpuscles under the conditions in which they normally exist.

IV. With the well-known fact that water or aqueous solutions will remove the hæmoglobins from the red corpuscles and render them so pale as to be scarcely visible I have nothing whatever to do. These conditions are never present in any of my experiments, in addition to which there exist unmistakable characteristic differences, which enable the technically educated to distinguish at once between decolourised corpuscles and such as have never possessed hæmoglobin.

V. Although the invisible disc of the mammal has not yet been detected in the circulating blood, its equivalent and analogue in the lower vertebrata is, under these conditions, readily demonstrated; for, notwithstanding that its cell-body is as invisible as the mammal disc, its nucleus is distinctly visible, and forms the means of its identification both within and outside the vessels, and the problem before us is precisely the reverse of one of decolourisation, for we have to bring into view, around a body which in the circulation and outside it presents itself and has been described as a free colourless element, a cell-body having the size and form of the cell-bodies of the ordinary red corpuscles, but devoid of hæmoglobin. Of the existence of the invisible corpuscle of oviparous blood we have therefore the crucial evidence furnished by its detection in the circulation.

## THE TREATMENT OF DEFLECTION OF THE NASAL SEPTUM.

By W. J. WALSHAM, F.R.C.S.,

ASSISTANT-SURGEON TO, AND DEMONSTRATOR OF PRACTICAL AND ORTHOPÆDIC SURGERY AT, ST. BARTHOLOMEW'S HOSPITAL; SURGEON TO THE METROPOLITAN FREE HOSPITAL; ETC.

THE treatment of deflection of the nasal septum, judging from the cursory way in which, even if mentioned, it is dismissed in the text-books and other works on surgery, does not seem to have received much attention from surgeons. This may in part be ascribed to the deformity being held as trifling. No doubt the mere bending of the septum to one or other side, and the slight lateral deviation of the nose which commonly accompanies it, are not in themselves very grave inconveniences, and were it not that the more or less complete blocking up of the nostril on the side to which the septum is deflected is apt to be followed by a train of very unpleasant symptoms, need not call for surgical interference. The symptoms most commonly complained of when the deformity has existed for some time are the disagreeable nasal quality of the voice, the stuffy feeling in the nose, the constant recurrence of colds in the head, and, when the lower part of the septum is affected, the unsightly red prominence visible just within the nostril. If the deviation is extreme, the symptoms are more distressful. The complete blocking up of the affected nostril may set up a chronic nasal catarrh, and this, together with the pressure of the bent portion of the septum, may cause obstruction of the frontal sinuses, nasal duct, or antrum of Highmore. Hence the dull pain or sensation of weight in the forehead, the running of the tears over the cheek, or, in extreme cases, dropsy of the antrum. Or the chronic catarrh may spread to the naso-pharynx and involve the orifice of the Eustachian tube, giving rise to deafness or noise in the ears. In one patient under my care the chief inconvenience was the peculiar noise made while eating, which rendered it, his parents said, most unpleasant to sit with him at table. In two cases, one under my own care and one under the

care of my colleague, Mr. Butlin, complete occlusion of one nostril had been produced by the adhesion of the deflected portion of the septum to the side of the nose, an adhesion apparently following ulceration of the adjacent surfaces induced by mutual pressure. In the first of these patients the nasal quality of the voice was especially marked, and considerable redness and œdema, probably due to obstructed venous return, existed at the junction of the lateral cartilages and the nasal bones, giving the lad the appearance of having recently had a blow upon the nose. Severe pain and frontal headache referable to the obstruction of the frontal sinuses were also complained of. The deflection is generally (in all the cases but one that have come under my notice—eight) the result of a blow or fall upon the nose, and is limited to the cartilaginous portion of the septum. It may, however, be congenital, and affect the bony part as well as the cartilaginous. Indeed a slight lateral deviation of the bony septum to one or other side of the middle line is, one may say, of almost normal occurrence, but is of course not attended with any inconvenience. Deflections may also occur in consequence of pressure from polypi, but to such the present remarks do not apply. When the result of accident, it is nearly always attended with some external deformity of the nose, generally a slight leaning to one or other side; in some instances, however, the lateral cartilages, in addition to a lateral deviation, are either depressed at their junction with, or partially dislocated from, the nasal bones, giving the nose an unpleasantly marked *retroussé* appearance. A dislocation of the septal cartilage from the anterior nasal spine to one or other side may also accompany the deviation. The affection is readily recognised. On looking into the nose a red fleshy mass may be seen partially or completely, according to the severity of the case, stopping up one nostril; whilst in the other there is a depression of the septum corresponding to the projection on the opposite side. The affection has been mistaken for a polypus or growth from the septum; but this can hardly happen if the precaution be taken of looking into the opposite nostril, or, when the deflection is high up, of searching for the depression with a bent probe.

The earlier operations undertaken for the remedy of the affection seem of a severity disproportionate to the inconveniences they were intended to relieve. Thus the nose has been split in the middle line, or the ala detached from the cheek, and the deflected portion of cartilage exposed by one of these means cut away. Chassaignac modified these procedures by performing what he calls subperiosteal resection. He made an incision along the lower border of the columnella, reflected back the mucous membrane from the septum, and shaved off successive pieces from the projecting portion until a sufficient suppleness was attained to allow it to be forced back into the middle line. He then reapplied the mucous membrane, and introduced a sponge into the nostrils to keep the parts in their new position. Blandin cut out a portion of the deflected part by means of an instrument somewhat resembling an ordinary leather button-hole punch. Zupprecht speaks in high praise of this method of removing the obstruction, and relates several cases in which it was successful. Dr. Goodwillie also recommends punching out a piece of the septum, and has had an instrument, a modification of Blandin's, made for the purpose, which he calls excising nasal forceps. Dr. Glasgow, of St. Louis, however, condemns the proceeding, affirming that it is liable to be followed by depression of the nose in consequence of the nasal cartilages falling in from want of the support of the septum; and that the nasal secretion, especially in scrofulous subjects, is apt to hang about and scab over the edges of the hole. No doubt when large portions of the septum are removed there is a tendency, as is seen in disease, for the nose to fall in. But this is not the case when the perforation is small. All must be cognisant of instances in which even a very considerable communication exists between the nostrils, and yet there is no deformity whatever. I have at the present time two cases of perforation of the septum from syphilis under my care in which two fingers could be passed through the perforation, but still no external deformity exists. Nor is there any other trouble experienced in consequence. But the removal of a very small portion of the bent cartilage suffices to restore respiration through the affected nostril; and when granulation has taken place, a still less aperture remains—much too small to induce any falling in of the nose. As a rule, however, it is not necessary to perforate the septum. Forcible straightening, and then keeping it in position by means of retentive apparatus, will suffice. The forceps

devised by Mr. Adams have in my hands answered admirably for the purpose. If there is any lateral or other deviation of the lateral cartilages, this can also be remedied at the same time as the septum is straightened by forcible manipulation with the forceps. Having straightened the septum and rectified the faulty position of the cartilages, these parts are well held in place by Mr. Adams' screw retentive apparatus. This little instrument, which consists of two lateral steel plates adjusted by a screw, can be worn for two or three days with little or no discomfort; and on its removal ivory plugs, properly shaped to the cavity of the nose, can be substituted for another week or two till the septum has been fairly consolidated in its rectified position. I have found the retentive apparatus as devised by Mr. Adams apt to produce ulceration of the lower part of the columnella in consequence of the pressure of its arms. This I have overcome by a slight modification in the form of the instrument—viz., by having the arms made a little longer, and with a lateral outward bow, so that when placed in position they do not touch the columnella. I have rectified six cases by these means, and in all except one, where there was great resiliency, with good results. The septum retains its median position, and nasal respiration in the affected side is free. When the cartilage is too resilient to be kept in its place, a portion of the bent part may be cut out by one of the forms of punch, or by the instrument suggested by Dr. Steele of St. Louis, which is a modification of the forceps of Adams and Blandin. It consists of a stout forceps shod on one blade, with knives set in a stellar form; the two blades are united, after the manner of obstetrical forceps, to facilitate the introduction of the instrument, and the cutting-blade is covered by a thin sliding shield, to protect the nostril during the introduction. With this little instrument a stellated division can be made through the mucous membrane and cartilage, and the divided septum be forcibly pushed into the middle line, and kept in position by retentive apparatus. Dr. Steele says that he has operated on two cases in this way with perfect success. The advantages claimed are, that perforation is avoided, and the resilience overcome by allowing the stellated divided cartilage to overlap. But the punch of Dr. Steele, like all instruments of the sort, is open to the objection that it causes more or less bruising of the soft tissues, and wounding of the mucous membrane on the sound side, and, should sloughing and necrosis follow, produces what it is intended to prevent. To obviate this I make the stellar division subcutaneously—i.e., insert a small knife, which I have had made for the purpose, under the mucous membrane, with the flat of the blade to the septum, and after moving it to and fro so as to detach the soft tissues from the cartilage turn the edge to the septum and make in it a stellar or other division. By this means all the advantages of Dr. Steele's stellar incision are gained without crushing or wounding the soft parts, except at the point of entrance of the knife, or wounding the mucous membrane of the opposite side. If the cartilage yields before the knife, it may be supported by the finger or any blunt instrument introduced into the hollow of the deflection through the opposite nostril.

In a case where much resiliency was present, Mr. Smith tells me that he succeeded in overcoming it by shaving off the mucous membrane and several thin layers of cartilage, but avoided a perforation by leaving the mucous membrane untouched on the sound side.

In cases in which the deviation depends upon the dislocation of the septal cartilages from the anterior nasal spine and contiguous portion of the nasal crest, I have found forcible straightening to succeed. In a patient in whom such a dislocation seemed to have occurred the cartilage was bent into position with an audible snap. It was then retained in the way above described. Should this method not succeed, that suggested by Dr. Goodwillie might be tried—i.e., to deflect the mucous membrane and periosteum, and then excise the dislocated end of the septum. From the ease with which the dislocation was reduced in my own case, notwithstanding the length of time it had existed, I should imagine that the cutting away of the dislocated portion can seldom be necessary.

A DRUGGIST in Hull was last week fined £10, with costs, for "illegally selling paregoric in the preparation of which methylated spirit had been used." Defendant admitted the charge, but alleged that the offence was committed in error.

## THE PATHOLOGY OF HEPATIC TUMOURS.

BY W. ROBERT SMITH, M.D., F.R.S. ED.

(Concluded from page 435.)

*Carcinoma telangiectodes* is distinguished by the great development of the smaller bloodvessels of the stroma, which frequently rupture, causing more or less extravasation. These tumours contain a large quantity of blood, are of a bright vermilion colour, and very soft in consistence.

*Colloid cancer* of the liver, which perhaps it will be convenient to notice here, is always a secondary growth, occurring either metastatically to a similar growth in the stomach and intestines, or as an extension from the peritoneum. In the one case, the nodes are distinctly seen to have originally been ordinary cellular cancer; in the other, the advance of the growth from the peritoneum is seen to have been principally through the subserous lymphatics, which under the peritoneal investment of the liver and gall-bladder are found filled with gray transparent colloid material. It is very important to remember that secondary cancer of the liver repeats all the histological characteristics of the pre-existing primary tumour; but although in the general characters of their constitution the nodes agree, yet they differ widely from each other both as regards the stroma and cancer cells. For example, the stroma may be well developed, forming a large proportion of the entire nodule, or it may be present in such small quantity that the bloodvessels appear to course nakedly through the pulpy cell mass; the cells also show the greatest variety in their number, shape, size, and arrangement; the number and arrangement will of course vary with the amount and character of the stroma, and being an epithelial growth, the cells may present all those forms which epithelial cells assume. The bloodvessels form a more or less close network, which is supported by the trabecule of the stroma; it varies in size and compactness, and for the most part the finer vessels which compose it are newly formed. According to Frerichs, this network receives its blood-supply from the hepatic artery. The original portal network is lost; only the larger branches of the hepatic and portal veins remain, and even these are often compressed and obliterated; whilst, on the other hand, the branches of the hepatic artery become dilated.

As regards the histogenesis of secondary hepatic carcinoma there is of course the greatest variety of opinion. One observer believes the cancer cells are derived from the hepatic cells and the epithelial cells of the biliary ducts; another, that they arise in the endothelial cells of the bloodvessels; a third, that they originate in the cellular elements of the connective tissue; but most probably the germs which were previously cellular elements of the primary cancer have been carried to the liver either through the bloodvessels or lymphatics, and there continue an independent existence, dividing and subdividing, and by successive encroachments on the liver parenchyma displacing the normal tissue, thus forming the nodules with which we are so familiar, and which may or may not undergo one of the forms of degeneration I have described.

(b) *Melano-sarcoma*.—Until very recently pigmentary tumours of the liver were classed with the carcinomata, but Virchow pointed out very clearly that this was an error, and demonstrated beyond doubt that these growths were really sarcomatous. He proved that the cells of which these growths are composed were not of epithelial origin; and if we are to consider the epithelial origin of cancerous growths to be their one great characteristic, then clearly these tumours do not belong to that class. They appear as primary growths in the liver with such rarity that observers have been found to question whether it ever occurs, though, as I think, without sufficient grounds. Both Bluck, in *Archiv d. Heilk.*, xvi., 1875, s. 412, and Frerichs, in *Klin. d. Leberkrankheiten*, ii., s. 319 *et seq.*, have recorded undoubted cases. But, as a rule, melano-sarcoma is due to a process of metastasis, the infecting source being, as we all know, in or about the eye or skin; it appears in the liver either as multiple nodes or as an infiltration, or both forms may be combined in varying proportions. Owing to the presence of these nodes the liver is increased both in size and weight, but in spite of this the hepatic tissue between the nodes is often reduced in volume.

The peculiar structure of these tumours is due to the fact—as will be noticed presently—that the capillary vessels, as far as their junction with the hepatic veins, are completely filled with black cells, and hence the characteristic whorled appearance of this portion of the vascular apparatus is manifested in black radiate figures of all sizes. In section under the microscope can be distinguished both stroma and nests or accumulations of cells. The stroma here and there is found to contain liver cells, which are in many cases distorted and stained with pigment. The real nature of these may be at once detected, not only by their peculiar characteristics, but by their direct continuity with the secreting network. In the finer trabeculae, spindle-shaped or stellate cells are seen, but these have no connexion with the hepatic cells proper. Surrounding the cells will be noticed the capillary membrane; and according to Rindfleisch the cells of this growth originate in these vessels, owing to a proliferation of the endothelium; the nodes are rich in delicate newly formed bloodvessels, which most likely proceed from the hepatic artery; whilst the vessels connected with the portal and hepatic veins are probably destroyed.

In the infiltrated form of melano-sarcoma the liver increases remarkably in size in a very short time, but undergoes no very striking alteration in shape; the external surface is smooth, although flattened protruberances appear where the growth has become dense and compact. On section the organ is seen to have preserved its characteristic acinous structure, but the acini are enlarged, and have a mixed colour composed of the normal hepatic brown and of the white and black of the new growth; the variable quantity of blood in the part also occasions a difference in the colour. Small nodules, more or less circumscribed, are diffused throughout the structure, and in consequence of many of the cells of the growth being free from pigment, or containing but little, a peculiar spotted appearance is presented, very much resembling granite, and hence the familiar name of "granite-like cancer." As regards the histology of infiltrated melano-sarcoma, Schuëppel relates a very interesting case in the *Archiv d. Heilk.*, ix., 1868, page 389, in which, at the autopsy of a patient who had suffered from melanotic growth of the choroid, he found both the liver and spleen enormously enlarged from the deposit of infiltrated melano-sarcoma; in the liver the capillaries of the portal system were everywhere crowded with cells of this pigment-growth, being at the same time absolutely devoid of blood; the capillaries were dilated, and the hepatic cells between them compressed and atrophied. In other cases in which the infiltration was very great the hepatic cells had completely disappeared. In this case there can be no doubt the germs of the disease wandered through the portal vessels from the spleen, and also that the infiltration was intra-capillary; it is still a matter of doubt whether in other cases the disease is transmitted through the capillaries of the hepatic artery.

(c) *Sarcoma*.—This growth has generally been regarded as carcinomatous, and there is perhaps some excuse for this as it is almost, if not quite, impossible during life to diagnose sarcoma or to distinguish it from true cancer. It is by no means a rare growth, and occurs for the most part metastatically. The nodes are so small in size or exist in such small numbers that they are often quite overlooked until revealed at the autopsy. In other cases these secondary deposits are found in such numbers or attain such a large size that the liver is enormously increased in volume. The growth occurs in one of two forms: either as deposits which appear as rounded elevations on the surface, or as a diffuse infiltration, which is generally the form with medullary lympho-sarcoma. The ordinary characters of hepatic sarcoma vary with the peculiarities of the original growth. Fibro-sarcoma and myo-sarcoma are both firm growths of a whitish tint, which exude on pressure a clear mucous liquid. Osteo-sarcoma is soft and of a medullary character, in contradistinction to the primary growth. Secondary lympho-sarcoma occurs most frequently as a soft medullary growth, rich in cells, and discharging on section a thick creamy juice.

(d) The last class of malignant tumours to which I shall briefly direct attention is the *adenomata*. They are very rare growths, but always primary, and occur as multiple tumours varying in size and scattered irregularly throughout the liver, more particularly near the surface. The larger nodes are distinctly encapsulated; the smaller ones, although circumscribed, are in immediate contact with the hepatic substance; they project a little above the surface, are yellow green or reddish in colour, are rather softer and more succulent than the liver substance, and discharge

on pressure a clear serous fluid. As a rule, adenoma of the liver is always a local disease, implicating neither the lymphatic glands nor distant organs. In a case, however, recorded by Professor Greenfield in the 25th volume of the *Pathological Transactions*, the lungs and mediastinal glands were both affected.

Microscopically adenoma is seen to be constructed on the type of genuine glands, especially of the tubular variety. The tubules of which it consists lie more or less parallel to each other, although in some parts they form a network and are connected with the hepatic ducts; transversely they are seen to possess a marked similarity to the convoluted tubes of the cortex of the kidney; they are lined with epithelium, whilst the lumen is filled with a tough mucoid mass of a yellowish or greenish tint. These tubules are held together by delicate connective tissue, which serves as a support to the delicate network of capillary vessels; the smaller ones, according to Schueppel, getting their blood-supply from the portal vein, whilst Rindfleisch believes it comes from the hepatic artery. The growths are more deeply stained with carmine than the surrounding tissues, and they appear merely to replace the ordinary hepatic cells. The tubuli of which adenoma are composed appear to arise from the rows of hepatic cells, whilst the glandular cells arise from the hepatic cells themselves; they increase in number by a process of division and subdivision, and then arrange themselves in a circular manner round a biliary capillary vessel, thus forming a glandular tubule. These tumours increase in size partly by offshoots from the original tubules, and partly by the coalescence of nodules which have arisen from the transformation of the trabeculae of hepatic cells. The nodules generally undergo softening, the cells becoming fatty and the serous capsule producing a certain quantity of pus, so that ultimately an abscess cavity may be produced which is liable to burst into the peritoneum, producing fatal peritonitis.

Cheltenham.

## ON A CASE OF EMPYEMA, WITH REMARKS.

By G. H. DARWIN, M.D., M.R.C.P.

THE teaching of Trousseau has of late years largely modified the treatment of both acute and chronic pleuritis, and has brought a class of severe and dangerous disease, more immediately within the reach of art, to the saving of many lives and the prevention of much and very serious deformity and loss of function. The grave results which follow from the distension of the pleural sac with fluid are not confined to the loss of power of expansion in the compressed lung, but vary in degree and kind with the side affected, being generally more serious in pleuritis of the left side than in that of the right. This of course depends upon the anatomical connexions; the displacement of the heart, which ensues when the left pleura is largely distended, drags upon the large vessels, and induces abnormal conditions in their course and calibre, and this alteration reacts upon the amount and force of the current of blood which passes through the organ, and consequently upon that which passes through the great vessels and the organs they supply. Thus the inferior vena cava has been found, on post-mortem examination, to be bent by the forcing over of the heart to the right side, until it has formed a right angle with its normal course, to the great (and in the case mentioned to the fatal) obstruction of the circulation. Hence arises obstruction to the return of blood from the lower extremities, congestion, stasis, and syncope; or, in other forms, the overtaxed right lung, already doing double duty as vicar for the compressed and useless left, becomes engorged, the pulmonary vessels are blocked, and dyspnoea and suffocation ensue, resulting, unless relieved, in death.

The efforts of nature herself must have early directed the attention of physicians to the question of evacuation, when the contents of the sac were clearly purulent; but for long they were followed with timidity, and not unless there were symptoms of severe dyspnoea, or even impending suffocation, was it considered advisable or necessary to resort to paracentesis. It was reserved for Trousseau (*Clinique de l'Hôtel Dieu*, p. 617) to show how the resources of art could come to the assistance of nature even in the acute stage of pleurisy, and by removing the fluid which

caused the oppression prevent the most serious consequences of the inflammation, and rescue the patient from impending danger and most serious and lasting deformity. Some of the advocates of this procedure have been led by their enthusiasm to assert that no case of pleuritis with effusion can be cured without this operation (Niemeyer). This is probably much too strong a statement, but it may be at least agreed that whenever the fluid products of an acute pleurisy induce distinct distension of the intercostal spaces, alteration in position of the heart, or any tendency to syncope or dyspnoea, its removal either complete or partial should be at once effected, and more especially if there are symptoms of hectic pointing to the formation of pus. In public or hospital practice this may be done as soon as the symptoms are seen to call for interference, but in private practice it is much more difficult, as the patient and his friends have to be consulted and made aware of the necessity, or at least advisability, of the operation, and they are not always ready to see the signs which indicate the need of such procedure at the time most favourable for it, and usually have a great dread of any opening into the cavity of the chest. Such was the case in regard to the patient whose history I am about to relate, and in consequence the operation was delayed beyond the most favourable period, a delay which led to some of the developments of the case, and most probably prolonged its continuance.

Thomas H—, aged sixteen years, apprentice in a Manchester warehouse, a thin, pale, anæmic-looking lad, 5 ft. 3 in. in height, weighing just before the attack 8 st. 3 lb., was seized, on Feb. 1st, 1882, with shivering of so violent a character that his fellow apprentice laid him upon a table or counter in the warehouse and held him down. He was taken home and put to bed, and his mother administered some simple household remedies for a cold, but finding him no better sent for me early next morning. He was then very feverish, lying on his back, with hot, dry skin, a pulse of 120 in the minute, and the temperature in the axilla 104° 8' F. Complained of pain across the chest, but more particularly on the left side; he could breathe with moderate freedom without any perceptible increase of pain, but the respiration was very quick (45 in the minute). On admission I found dulness on percussion over the lower two-thirds of the back of the left lung, and on auscultation loud tubular breathing, with crepitation and bronchophony. The left side did not expand equally with the right; the tongue was coated with thick white fur, and he suffered from a rather severe diarrhoea. The history that I obtained was that three days previously (Jan. 31st) he was running away from a man, when he fell over a large package, and the man following fell over him, falling with his knees on the lad's chest. The man was a stout, heavy fellow, weighing, the lad said, 15 st. On Feb. 4th he expectorated glairy, rusty-coloured sputa; he had a short dry cough, and there was delirium, also sordes on lips, with more dulness on percussion. From this time the case followed the usual course of pleuro-pneumonia, until Feb. 20th, when he was much troubled with dyspnoea; the left side did not move as the right did; there was dulness on percussion almost all over the left side, with absence of vocal resonance and diminution of the respiratory murmur. I proposed to make an exploratory puncture in the chest, but the parents would not sanction this, and five days later he had violent shiverings during the night, with great dyspnoea and rapid breathing. Pulse small, 120 in the minute. The heart was at this time displaced to the right. I again pressed for permission to puncture, but was still refused. The patient was now rapidly getting worse, and I therefore requested Dr. W. H. Barlow to see the case with me. He agreed with my diagnosis, and supported my request; but the friends being yet unwilling it was arranged to see him again in a week. On March 11th Dr. Barlow again saw the case with me. There had been considerable shivering, with night sweats and frequent cough. The cardiac impulse was between the fifth and sixth ribs on the right side. Pulse 115, small and weak. Paracentesis thoracis was performed in the space between the latissimus dorsi and the trapezius, by the lower angle of the scapula, and in the seventh intercostal space; about half a pint of pus was evacuated by the cannula, and then the opening was enlarged and a drainage-tube inserted. I saw him again in the evening, and he said he felt better, but the dyspnoea was very little relieved. The next day there was a very little discharge of pus, so I washed out the tube with a solution of carbolic acid. On the 13th Dr. Barlow saw him again, and made a counter-opening about three

inches more anteriorly in the same interspace. A drainage-tube was passed through from one to the other, and the ends tied together. A considerable quantity of pus escaped, and we hoped it would have been effectual; but on the 15th there was more shivering, and on this date a small fluctuating tumour was seen in the same costal interspace as the openings already made, but about two inches more anteriorly and consequently lower; this was at once opened, and gave exit to about a pint of pus, quite sweet and laudable. A drainage-tube was inserted, and the three openings were all covered with a poultice. From this time a considerable drainage of pus took place, and the heart seemed to have moved more towards the median line, when on March 24th I was sent for in great haste, the message stating he was dying. On arrival at the house I found that he had recovered from the urgent symptoms that had been the cause of the message, and heard that he had been coughing rather heavily, when suddenly he gulped about a teacupful of pus, which almost suffocated him. From this time he improved rapidly, had but little cough, but would now and then get up a mouthful of pus, which, however, gradually became less. The external wound ceased to discharge, and when the drainage-tubes were removed gradually closed. On May 13th he was able to take pretty long walks and was gaining flesh rapidly, while the left side expanded freely and the respiratory murmur was heard in every part. There were still some slight bronchial râles, and he occasionally brought up a little purulent matter, but had not done so for a week or ten days, and was to all intents convalescent. The recovery is now (Sept. 20th) quite complete.

In the consideration of this case, the question that first arises is as to the connexion, if any, between the injury to the chest and the inflammatory symptoms which so speedily followed. Was the sequence a mere coincidence, or was the relation that of cause and effect? The point is one of doubt and difficulty. It is clear that no fracture of any rib was detected, nor are there now any signs that such an injury has ever existed, and yet it is difficult to conceive how, in the absence of such a lesion, inflammation could originate from such an accident. Our knowledge of nervous pathology, however, forbids us to say that such a result is not possible, improbable as it may appear *prima facie*.

It has been shown by Brown-Séquard<sup>1</sup> and others that an irritation to the periphery of a nerve may produce an inflammatory affection of a distinct and distant organism. But would such an injury as that recorded in the above case produce an irritation sufficient for this purpose? In the present state of our knowledge, we must be content to leave the question undecided and merely record the fact.

The progress of the case after the operation of paracentesis thoracis deserves a little notice. Firstly, there was the free gush of pus for a short time; then cessation, to be renewed when the tube was cleared for a very brief period; after this a gradual draining away of healthy pus for some days; then followed the creation of a counter-opening and the insertion of a drainage-tube after the manner of Chassaignac, resulting in the continuous drainage of a small quantity of pus; and finally the spontaneous pointing of the abscess, not at the point which is the usual place of natural selection, in the fifth interspace, but lower down in the seventh. This makes it quite clear that we had to do with a case like those described by Fräntzel, in which "the pleural cavity was subdivided into several sacs by false membranes," and which would probably have needed to be broken down by the introduction of a catheter had not the pus so opportunely found a free vent through the lung.

Professor Morgan of this city<sup>2</sup> has given an account of two cases in which this method was adopted with excellent results, and in the same paper he advocates the treatment of the collapsed lung by the respiration of compressed air. In one of these cases the "tough fibrous ribbons which subdivided" the cavity "into pouches" were perforated by a long trocar and cannula made for the special purpose; in the present case a long bladder trocar was the means used to make the counter-opening. The gush of pus into the bronchi was so sudden and so copious as to endanger life for a few moments from suffocation; it is generally gradual and the openings of communication so
